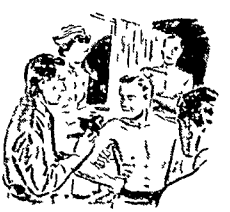
The routine use of Prostigmin Methylsulfate 'Roche,' 1:4000 provides a convenient and effective means of preventing postoperative abdominal distention and urinary retention. Since many hospital staffs have been drastically reduced, every precaution which can be taken to obviate troublesome postoperative procedures is of major importance. Any measure that affords smoother convalescence for the patient and reduces the work of the staff, is a doubly valuable expedient. To minimize discomfort due to abdominal or bladder atony inject 1 cc of Prostigmin (1:4000 solution) intramuscularly immediately after operation. Follow with 5 similar 1-cc injections at 2-hour intervals. Additional injections may be given if necessary.

HOFFMANN-LA ROCHE, INC. • ROCHE PARK • NUTLEY • NEW JERSEY

PROSTIGMIN 'ROCHE'



2153 Lederle employees and more than 500 fo
mer employees now in the armed forces, sha
the honor symbolized by the Army-Navy "E"

From research laboratory and production line more than fifty different therapeutic and prophylactic products are included in Lederle's steadily growing contribution to the war effort.

Sulfonamide Tablets in soldiers' kits.

Tetanus Toxoid for the production of active immunity to tetanus.

Life-saving blood plasma.

Blood typing for eve soldier's identification

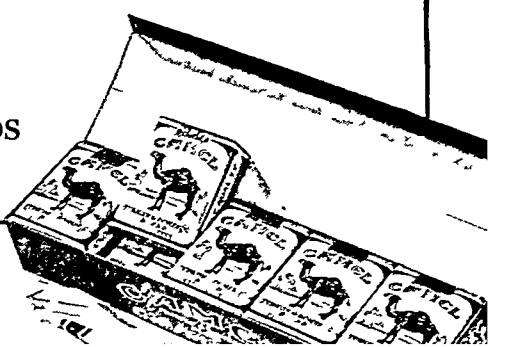
Make the Gift Worth the Giving

Your gift of Camels to a service man has this to commend it:

First, cigarettes are the gift keenly appreciated in the armed forces.

Second, Camel is the brand the men say they prefer above all others.*

So make your gift Camels—the cigarette millions favor among all brands for smooth mildness, mellow, appealing flavor.



Send Camels by the carton—the way they're featured at your dealer. See or telephone him today.

• • •

*With men in the Army, the Navy, the Marine Corps, and the Coast Guard, the favorite cigarette is Camel. (Based on actual sales records in Post Exchanges and Canteens.)

Decholin
REG U S PAT OFF
COUNCIL ACCEPTED FOR TWELVE YEARS

. . . IN NONCALCULOUS CHOLANGITIS

The first step in the treatment of acute cholangitis is to increase drainage into the duodenum. It is best accomplished by inducing a copious flow of thin liver bile. Free drainage tends to discourage ascent of infection, reduce subjective discomfort, and shorten the clinical course.

Decholin sodium offers a dependable means of increasing biliary flow and improving drainage. Injected intravenously, it creates an intense hydrocholeresis increasing bile flow as much as 200 per cent. The thin liver bile so produced washes before it undesirable debris and products of infection.

Oral treatment with Decholin tablets has a milder effect and is useful for prolonged medication. Decholin should not be employed in cholangitis due to calculi, and is contraindicated in complete obstruction of the common or hepatic bile duct.

SUMMER PRURIGO

Calmitol (chlor-iodo-camphoric aldehyde, levo-hyoscine oleinate, and menthol in an alcohol-chloroform-ether vehicle) exerts its antipruritic action by blocking cutaneous receptor organs. It is protective, bacteriostatic, and induces mild hyperemia.

ITS specific antipruritic influence gives Calmitol a wide range of therapeutic applicability, especially during the summer months. More hours spent out-of-doors sharply increase the incidence of contact dermatitis, food rashes, summer prurigo, and intertrigo. When prescribed in these conditions, Calmitol instantly allays the torturing discomfort of the associated itching. It obviates the need for scratching, thus prevents traumatic lesions and actually hastens resolution of the original condition under treatment. Calmitol is also widely used in the treatment of urticaria, drug rashes, eczema, pruritus ani and vulvae.

Thos. Leeming & Co. Inc.

155 E. 44th St. New York, N. Y.

nascent OXYGEN for LEUKORRHEA

CLINICALLY TESTED*: (a) eliminates unpleasant odor of discharge; (b) cuts down or eliminates irritations inside and without the vagina; (c) reduces quantity and density of the discharge, including that following cauterization ... Non-irritating and non-toxic in contradiction to the arsenic and picrate preparations, is equally effective and actually soothing, especially in the (a) infantile vagina, (b) senile vagina, (c) trichomonas vaginalis vaginitis of pregnancy.

*Barrows: N.Y.St.Jr.Med. Vol. 41, 1/15/41

nascent OXYGEN for DRESSINGS

CLINICALLY TESTED*: As a surgical dressing: gauze, saturated with STA-O-GEN (a) does not adhere to wounds, (b) reduces discharge, (c) eliminates unpleasant odor, (d) wounds heal faster and appear healthier, (e) dressings are easily applied, continue effective longer and cause no burning or pain when changed, (f) there is no irritation of the skin about the wound edge, (g) particularly effective around perianal region in postoperative work (h) stainless.

*Cowett: Meet, N. Y. Proc. Soc. 4/15/42

STA-O-GEN is a bland ozonide of olive oil. On application, it releases nascent oxygen continuously for hours—deodorizing, germicidal, fungicidal, healing. Available in Liquid or Ointment; also Vag-I-Caps for leukorrhea prescription. For your convenience, druggists may obtain from any jobber.

Ertronize early

Even though *Ertronization* has proved effective in cases of arthritis of long duration, the literature indicates that beneficial results are obtained sooner when ERTRON is administered early.

Ertronization should be started as soon as the diagnosis is made.

Ertronize adequately

The dosage of ERTRON should be gradually increased over a period of two or three weeks to the *Ertronization* level (average 6 capsules a day), and maintained at this level throughout treatment.†

Ertronize continuously

The beneficial systemic action of ERTRON is dependent upon non-interruption of the treatment schedule. A period of several months may often be required for optimum systemic response.

ERTRON is the only high potency, activated, vaporized ergosterol (Whittier Process)—made only in the distinctive two-color gelatin capsule.

Available in bottles of 100 and 50 capsules.

ERTRON *is promoted only through the medical profession.*

†Complete details of dosage and mode of administration will be sent to physicians on request.

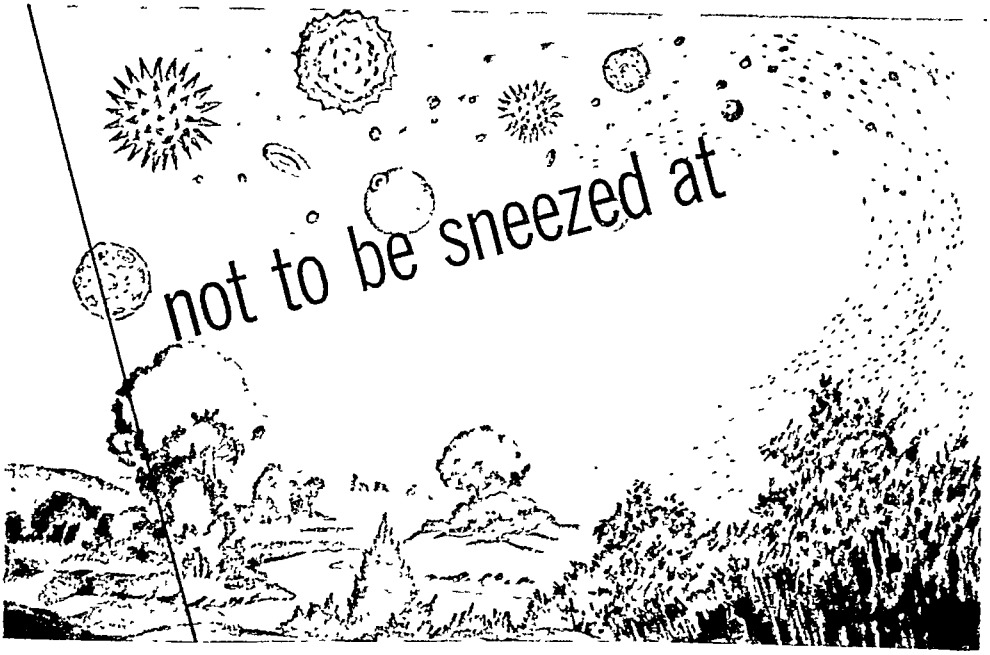
FOR GASTROINTESTINAL DISORDERS
Tablets ALMUTAL No. 1

ANTACID • ADSORBENT • ANTISPASMODIC

A balanced antacid formula for controlling gastric hyperacidity and eliminating intestinal toxemia; suggested in the treatment of spasm of the pylorus and the intestines, toxic bowel, colitis, nervous insomnia and nervous indigestion. Write for samples and literature.



MUTUAL PHARMACAL COMPANY
INCORPORATED
821 S. STATE ST. SYRACUSE, N. Y.

Each Tablet Contains:

Magnesium Trisilicate, Hydrated	5 gr
Aluminum Hydroxide	2 1/2 gr
Phenobarbital	1/8 gr
Atropine Sulfate	1/1000 gr

Tablets Almutal No 1 are orange colored and orange flavored

Price: **$2.70 per 1000** list

The annual pollen blitz brings sneezing and respiratory distress for your hay fever patients, and an increase in asthmatic seizures. From "Spring to frost" you will appreciate the value of Searle Amodrine in controlling the symptoms with a minimum of side reactions.

Combines the well known antispasmodic value of Aminophyllin (Searle) with the vasoconstrictor activity of racephedrine hydrochloride and the sedative effect of phenobarbital.

Supplied in bottles of 100 and 1000 tablets, plain or enteric coated (the latter for delayed effect).

THESODAN
Brewer
The ORIGINAL ENTERIC-COATED TABLET OF THEOBROMINE SODIUM ACETATE

EFFECTIVE
*in Coronary Artery Disease and Edema**

Clinical experience and carefully controlled studies in *humans* have definitely proven the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal diseases, and the value of the enteric coating in permitting adequate dosage without causing gastric distress.

Supplied—in 7½ grains with and without Phenobarbital ½ grain; in 5 grains with Potassium Iodide 2 grains and Phenobarbital ¼ grain (cost approximately $1.50 per bottle of 100 tablets); and in 3¾ grains with and without Phenobarbital ¼ grain (cost approximately $1.00 per bottle of 100). Capsules, not enteric coated, are available in the same potencies for supplementary medication.

*Literature giving confirming bibliography, and physicians samples will be furnished on request.

Gratifying Relief

of distressing symptoms in **CYSTITIS**

PYELONEPHRITIS

PROSTATITIS

URETHRITIS

The prompt symptomatic relief provided by Pyridium is extremely gratifying to the patient suffering with distressing urinary symptoms such as painful, urgent, and frequent urination, tenesmus, and irritation of the urogenital mucosa..

Clinical experience extending over more than a decade, as reported in the published literature on Pyridium, testifies to its prompt and effective action, and its freedom from narcotic or irritant effects.

Pyridium is convenient to administer, and may be used safely throughout the course of cystitis, pyelonephritis, prostatitis, and urethritis. *The average oral dose is 2 tablets t.i.d.*

More than a decade of service in urogenital infections

PYRIDIUM

(Phenylazo-alpha-alpha-diamino-pyridine mono-hydrochloride)

ZymenoL

Brewer's Yeast Emulsion

Controls Summer Diarrhea

WITHOUT CONSTIPATING EFFECT

ZymenoL, containing pure, whole, aqueous BREWERS YEAST including the natural enzymes, controls ***Common Diarrhea*** on the following dosage:

One teaspoonful every hour, reduce after few hours to individual need.

ZymenoL promptly overcomes the irritating watery stool of Diarrhea and restores normal evacuation with a bulky, less toxic stool WITHOUT CONSTIPATING EFFECT because of its two fold natural action;

1. **THE ENZYMES restore near fermentative fecal bulk and a less toxic bowel flora.**
2. **COMPLETE NATURAL VITAMIN B COMPLEX restores normal tone and motility in either the hyper- or hypotonic bowel.**

SPENCER
Breast Supports

For Pre-Natal and Nursing

Spencer Maternity Support Spencer Nursing Support

Each Spencer Breast Support for pre-natal wear, like *all* Spencer Supports, is *individually designed* for the one patient who is to wear it, to lift and hold breasts in natural, healthful position, without compression.

It improves circulation—protects delicate inner tissues—helps prevent outer skin from stretching and breaking—aids breathing—improves appearance—encourages erect posture. Easily adjustable to increasing development.

Painful, engorged breasts are often relieved by a Spencer, as it allows veins to empty easily. (A further advantage is gained later in increased milk supply from equalization of circulation during pregnancy.)

GUARDS AGAINST CAKING AND ABSCESSING

The Spencer Breast Support for nursing mothers provides protection against caking and abscessing. Closes in front for nursing convenience.

Spencer Supports are never sold in stores. For a Spencer Specialist, look in telephone book under "Spencer Corsetiere" or write direct to us.

METHYLTESTOSTERONE is now offered in the form of METANDREN LINGUETS* designed for sublingual administration. Clinical investigation indicates that this method of absorption through the oral mucosa results in greater effectiveness when compared with ingestion therapy. ***METANDREN LINGUETS*** are absorbed directly into the circulation, thus side-tracking the liver and permitting all systemic effects characteristic of ***Androgens.*** Dosage is usually ⅓ to ½ less than that required when methyltestosterone is administered via the gastro-intestinal tract.

METANDREN LINGUETS produce qualitatively the same biological effects as ***PERANDREN*** (testosterone propionate) and have therefore the same indications in all conditions due to *testicular deficiency.* Because of their pleasant taste, convenience of administration, and smaller dosage requirements, ***METANDREN LINGUETS*** are presented as a significant advance in androgen therapy.

*Trade Marks Reg. U.S.Pat.Off. "Metandren Linguets" identifies the product as methyltestosterone of Ciba's manufacture, for sublingual administration.

CIBA *Pharmaceutical Products, Inc.*
SUMMIT, NEW JERSEY

BELBARB

AN *Excellent* SEDATIVE and HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg Arch f exp P & P CLX 276) renders possible attainment of desired effects with relatively small doses thus avoiding 'hang over' and other unpleasant side actions In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids*

Indications: Neuroses migraine functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids equivalent approximately to 9 minims of tincture of belladonna

Belbarb No 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

THE GLORIOUS "FOURTH" PAIR OF SHOES

NO! . . . we are not dreaming of post-war freedom when Americans may again buy a fourth pair of shoes, or a fifth pair, or even a carload if so minded—we are thinking of today; of making three pairs of shoes add up to four or more.

Of all the coverings worn by humans—shoes take the worst beating. They must withstand rain, snow, sand, mud and sun. They must stand up under crushing weight, and be practically immune to body moisture, body acids and heat.

To take such punishment, the quality of materials, workmanship, and proper fitting must be of the best. And every fraction of such superiority in three pairs of better shoes adds up to an equivalent of a "fourth" pair in terms of length of service.

YEARS—WITH VITALITY

Our Nation is "aging." The 1940 census figures reveal approximately 9 million persons over 65 years old in the United States.

Older persons are replacing younger workers during the war period. Maintenance of good health among individuals past middle age becomes a matter of urgency. An important factor in such maintenance is the problem of adequate nutrition.

Simple, well-balanced, easily digested, quality nourishment is of paramount importance to the upkeep of their strength and vitality.

As an integral part of your regimen for the aged, Horlick's supplies pure, full-cream milk, plus extracted nutrients of wheat and malted barley in powdered, concentrated form.

Horlick's is delicious whether prepared with milk *or with water.*

Also ideal for between-meals' feeding — Horlick's Tablets — available in conveniently carried *(25¢)* oval flasks.

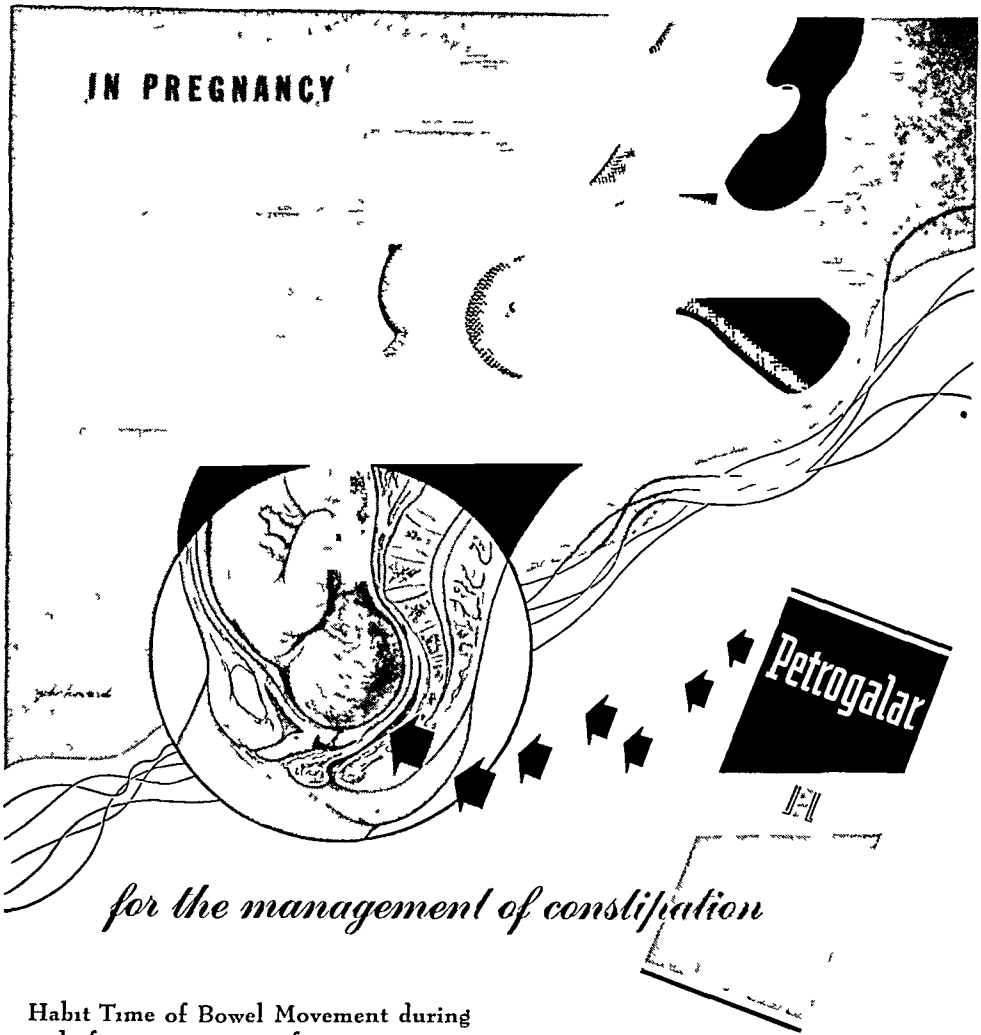
VOLUME 43 JULY 1, 1943 NUMBER 13

Editorial

The American Ferment, II



The dominant note in American life today is the pursuit of security. On battlefronts scattered over the whole world, in the deliberations and acts of legislative bodies, in the daily journals, the pursuit follows its bloody, windy, or wordy course toward a better world for men to live and die in.

The function of the new Planning Committee for Medical Policies of the Medical Society of the State of New York is to study trends in American life in order to advise the Society how medical policies and practice may best serve the public interest. The Committee commences its work at a time when there is before both houses of Congress an "American Beveridge Plan" in legislative form designed to provide postwar social security from the cradle to the grave. The proposal covers the major economic hazards of the average American throughout his lifetime. It is said to assure medical care and hospital service without interfering with free choice of patient, doctor, or hospital. The sponsors of the bill are Senator Wagner of New York, Senator Murray of Montana, and Representative Dingell of Michigan. The bill is said to call for a payroll tax of 12 per cent divided equally between employers and employees, with administration of the medical aspects of the national health and hospital care by the U.S. Public Health Service.

Many will recall that in 1937 the question of adoption of medical expense indemnity insurance was before the House of Delegates of the Society. The committee which sponsored the report laid down the thesis that it was the duty of the lay public to develop plans to finance medical care and that it was the province of organized medicine to maintain the standards and quality of such care.[1] Apparently the public, through its elected representatives, is preparing to do just that through the medium of social security legislation.

Professor Chas. E. Merriam, addressing the A.M.A. delegates at Chicago on June 7, said of the "American Beveridge Plan" that it

> ". . . . was based on the proposition, backed up by present indications, that the national income would attain and maintain a level of about $120,000,000,000 a year.
>
> "We literally stand at the gates of an age of plenty, key in hand, fumbling at the lock," Professor Merriam declared. "General objectives have been outlined, but we now face the patient preparation of more detailed plans and specifications, programs of legislation and administration, national, state, and local, by public and private agencies.
>
> "The winning of the peace in fullest measure calls for unity and good-will—the price of victory in war and peace alike.
>
> "If we can follow, and I believe we can, the way indicated alike by our ideals and our interest, we can anticipate an economy which puts a sound floor under social security, including health, housing, education, employment, and that has no ceiling above on initiative, enterprise, and achievement.
>
> "It will be found that our American traditions of justice, equality, liberty, and the pursuit of

for the management of constipation

Habit Time of Bowel Movement during and after pregnancy is of paramount importance to the patient's well-being and comfort. Pressure of the fetus upon the intestines, and lack of exercise are factors which induce constipation during pregnancy, postpartum and lactation.

Epidemic Keratoconjunctivitis

For reasons somewhat intangible, diseases that previously have been dormant and infrequent sometimes become epidemic and sweep a nation. In the case of generalized infections or infections involving a secretory or excretory tract, such as the respiratory or gastrointestinal systems, this picture is not [illegible] but we do not customarily associate such epidemic infections with a localized organ like the eye. Yet the disease now known as epidemic keratoconjunctivitis is just such an infection, which, beginning on the West Coast,[1] speedily traveled throughout the country, soon making its appearance in the East.[2] Although it started as an industrial disease, this eye infection is no longer so limited.

As its name implies, the cornea as well as the conjunctiva is involved in the great majority of cases. The ocular manifestations are pronounced edema of the lids and conjunctiva with bulbar chemosis, follicular conjunctivitis, and corneal opacities. Ocular discomfort is prominent and lacrimation is excessive. A preauricular lymph node is frequently enlarged, as, in many cases, are the submental and anterior cervical nodes. Conjunctival smears and scrapings reveal a preponderance of mononuclear cells, not polynuclear leukocytes. Cultures are sterile for bacteria, but a virus has been incriminated. Serums of convalescent patients have been shown to contain neutralizing substances for this virus. Because of this finding, convalescent serums have been used therapeutically with some promise of success.[3]

A disease with frequent corneal involvement must be treated with circumspection. Isolation and quarantine are invaluable prophylactic measures and must be immediately instituted to safeguard the contacts in the community, industrial or otherwise. This is all the more important since as yet there is no specific cure, with the possible exception of convalescent serum, which is difficult to obtain. The importance of immediate diagnosis is essential to early quarantine, which is the only certain safeguard for the prevention of epidemic keratoconjunctivitis.

Breast Milk Deficiencies

For centuries it has been generally accepted that breast milk is the ideal food for the human infant. This tradition was unchallenged until the advent of metabolism into the field of pediatrics. In recent years the caloric, water, protein, mineral, and vitamin requirements for optimal infantile growth have been rather accurately calculated and recorded.[1] It must constantly be remembered that lactation is a reflection of the maternal diet, the adequacy of which determines the value of the milk so produced.

Breast milk is low in protein content. About 8 per cent of its calories are derived from that important fraction. Premature and immature infants often cannot maximally thrive on the limited protein quota of human milk.[1] For this reason protein reinforcements from other sources are often added, either in the form of dehydrated milk or by admixture with some other form of cow's milk. That human milk, like cow's milk, is very poor in iron content has long been known. The vitamin content of human milk may also be insufficient for the needs of a rapidly growing organism.[2] A most important recent contribution is the demonstration that calcium utilization by the premature baby may be subnormal on a diet of human milk.[3] On the other hand, the retention of calcium is tremendously improved and becomes optimal when cow's milk is the source of calcium and phosphorus.[3] These minerals are indispensable for the normal growth of the skeletal system and other tissues. Like a favorable nitrogen balance, high calcium and phosphorus retentions are indices of good nutrition.[3]

It should not be inferred that breast milk is not a good food for the human infant. Nor should the conclusion be drawn that cow's milk, skillfully blended by the pediatrician, is superior for the general metabolic needs of infants. It is wise, however, to be cognizant of the limitations of human milk in certain instances, as in a rapidly growing organism such as the premature or immature infant. These limitations can be overcome by the addition of the necessary ingredients indicated by recognized deficiencies.

happiness are not obstacles to prosperity but its essential conditions, underlying all genuine advance. We can unite security and freedom."[2]

To which General Fred Rankin added that organized medicine

". . . . cannot disregard the growing interest of the public, the government, and various lay groups in the administration of medical care. Nor," he added, "can we afford to engage in a struggle for domination.

"The solution to these problems and the attainment of our objectives," he asserted, "do not lie in that direction. They can be approached more expeditiously by a willingness to share their responsibilities and a readiness to cooperate in their consideration.

"The importance and urgency of these various problems commend the immediate establishment by this association of suitable agencies for their investigation. In the institution of these agencies the purpose and vast significance of their function, the sharp delineation of their problems, and the need for their collaboration with others should be emphasized."[2]

But what is social security? Homer Folks, writing in the *S.C.A.A. News*, says in part:

"The phrase 'social security' is a recent arrival. It has no one clear-cut definition. It would seem that it should mean 'Individual Security Through Social Action.' A large part of individual insecurity obviously arises from causes beyond the individual's control.

"Some men are born poor; some achieve poverty; and some have poverty thrust upon them; and the last is by far the largest group. Obviously society may operate in various ways in reducing individual insecurity. . . . .

"But social insurance is only one form of social security. The *Beveridge Report* is in fact entitled 'Social Insurance and Allied Services.' What are some of these 'allied services'? How valuable are they, how long have they existed, how dynamic are their contributions to social security, how susceptible are they to further extensions? . .

"Clearly, nothing has promoted social security, dependability of income, personal adequacy, and efficiency in meeting the responsibilities of life more than the prevention of smallpox, tuberculosis, diphtheria, syphilis, catastrophes related to childbirth, pneumonia, and the like. No provision for the care of the sick and the maintenance of widows and orphans can compare for a moment, as a measure of social security, with the prevention of disease. We face here a fundamental difference in philosophy and in method, which seems to have been very often greatly underestimated, or even overlooked, by the promoters and framers of social insurance measures. The forgotten factor is the dynamic value of preventing misfortune, loss of income-producing capacity, and social insufficiency, instead of, to a degree, regarding such losses as inevitable and devising measures for spreading their incidence over large groups and periods of time.

"It is not fanciful to see an 'insurance psychology' which loses sight of that valuable distillation of human experience—an ounce of prevention is worth more than a pound of cure. It is, of course, not a question of 'either or'; it is a question of practicabilities and possibilities of both at any given time. . . . .

"Certainly one of the most important tests by which all these social security plans should be judged is as to how, and to what extent, they promote public health. It must be admitted that, on preliminary reading, both the British and the American plans are, as compared with their other subject-matter, definitely vague as to the all-important subject of public health. The term 'public health' may be considered as including mental hygiene, though that term does not seem to appear in either report. Mental disorder certainly calls for a lot of hospital care, roughly equivalent to all other types of hospital care put together. It breaks up more families, destroys more individual efficiency, spoils more personal plans, and causes more social wreckage than any other type of illness, possibly more than all other types put together. The fullest application of our all too scanty knowledge of the causation, possible prevention, and suitable diagnosis and treatment of mental disorders should certainly have a large place in plans to promote individual security through governmental action."[3]

The participation of the State of New York in medical health and welfare services as a cooperative enterprise with voluntary agencies and the medical profession of the state has anticipated much of what is now being proposed as a national social security plan. The extent of that participation was shown by a previous editorial in this JOURNAL.[4] It is to be expected that the exigencies of a nation at war will require the extension of already existing and proved enterprises, a widening of the field of voluntary medical indemnity insurance, a fluid system of private practice prepared to integrate itself into the larger social mechanisms, the blueprints of which are now being introduced in the Congress.

SUMMARY OF PRESENT TREATMENT OF WOUNDS AND BURNS

CAPTAIN REYNOLDS HAYDEN, MEDICAL CORPS, U.S. Navy

THE mobile character and greatly increased aerial activity of the present war has necessitated considerable change in medical procedure in combat areas. While the first emergency treatment of casualties presents the same problems as heretofore—control of hemorrhage, treatment of shock, and prevention of infection—wounds of the present war are frequently multiple, severe and extensive, predisposing to infection, and accompanied by severe shock. Medical units in forward areas must now be mobile and prepared to do what was previously considered "hospital surgery" at a main dressing station near the firing line. Surgeons attached to these units must be qualified to do traumatic surgery of any part of the body.

Effects of Projectiles

The effects of high velocity projectiles upon the body tissues are not generally appreciated by the civil surgeon. In the immediate vicinity of the explosion of an aerial bomb, the bomb fragments have a velocity of some 5,000 feet per second. These fragments are irregular in shape and size and frequently cause multiple or great gaping wounds with extensive tissue destruction.

The modern high velocity rifle bullet produces a variety of wounds. Those of entrance and exit may be small, and the wounds readily heal. If bone is struck, however, the bone fragments act as projectiles and the wound of exit is large, or there is great destruction of the deeper tissue. Ricocheting bullets and metal fragments cause the most severe and revolting wounds.

Emergency Treatment

The majority of casualties need $1/2$ grain of morphine promptly. More than this amount is likely to increase the symptoms of shock and may depress the respiratory center. Intravenous injections may be used when relief of pain is urgent. An intravenous dose of $1/6$ to $1/4$ grain, diluted to at least 1 cc. with sterile water and injected over a period of a minute or more, will reduce pain almost immediately. Morphine should not be used in head injuries unless they are complicated by extensive injuries elsewhere. It should never be used routinely.

Our conception of wound infection has changed during the present war. We now know that many of the more virulent organisms are not introduced into a wound by the missile but are introduced when the wound is being dressed. The greatest danger of infection is from the fingers, nose, or mouth of the person who first inspects and treats the open wound.

At the first dressing, hemorrhage is controlled, the wound grossly cleaned, and powdered sulfonamide sprinkled or poured into the wound. A sterile occlusive dressing is then firmly applied. The severely wounded are given 2 Gm. of sulfadiazine internally immediately after injury followed by one Gm. every six hours as indicated. First aid packets now contain a package of crystalline sulfanilamide and another of sulfadiazine tablets for this purpose.

We have found that gauze moistened with saline or azochloramid solution gives the best results as a wound dressing because free drainage is permitted. Dry dressings tend to trap exudate beneath an impervious layer of caked powder while vaseline gauze tends to dam back the exudates, the sulfonamides losing their potency in each case.

Naval experience has definitely shown the value of the sulfonamides locally in the prevention of wound infection. Crystalline sulfanilamide has been quite satisfactory for this purpose. Sulfathiazole has been unsatisfactory because it cakes, forms a plastic cast, and prevents drainage. Microcrystalline sulfathiazole, however, is more satisfactory locally than sulfanilamide.

Recent investigations have indicated that the sodium salts of sulfadiazine or sulfathiazole, because of their much greater solubility, may be more efficacious when used locally for prevention of wound infection than other sulfa preparations.

In deep wounds, a sulfonamide suspension is injected into the wound pocket.

No attempt should be made to remove metal fragments from wounds at the first dressing unless the fragments are readily accessible. The incidence of cellulitis or severe infection is apparently not increased by even large metal fragments.

Except in superficial wounds, it is imperative that no wound closure be attempted at the first dressing. The great majority of wounds which have received primary suture at the first aid station become badly infected. Following local treatment, sutures may be placed, left long, and tied after the third day if there is no infection, or secondary closure may be done later when it is indicated.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

Doctors' Households Urged to Set Example in Waste Fat Salvage

The importance of saving waste household fats in order to salvage their glycerin content should be apparent to every physician. The doctor's kitchen, like that of every other family in town, can supply at least a tablespoonful of fat a day—from meat drippings, from rendered trimmings, or fat skimmed from the soup kettle and no longer good for food. If that much were retrieved in every household and taken to the meat stores which collect the fat for the renderers, the amount saved would exceed the national goal of 200,000,000 pounds for 1943.

Glycerin is indispensable in the manufacture of munitions because it is the source of both nitroglycerin and dynamite, the first of which provides the explosives for propellants and the second the means of military demolition. Tanks, ships, and planes last longer because of paints containing glycerin. It is used as an anti-icing fluid for the propellers of fighter and bomber planes. The shock absorbers of jeeps and half-tracks, the recoil mechanisms of big guns, and the firing mechanisms of depth bombs all contain glycerin.

Glycerin has an important place on the medical front, too, in both war and peace. It is one of the best-known and widely used medical materials. There is scarcely a branch of therapeutics in which glycerin does not play a part. An average of more than 3 pounds of glycerin per hospital bed per year is used in our American hospitals. And an analysis of 15,063 prescriptions made prior to the war in a single American city showed that, with the sole exception of water, glycerin was the most-used liquid ingredient.

In military medicine the role of glycerin continues to grow. Even before we entered the war, large quantities were shipped by the American Red Cross to England. In the requests made to organized *medical groups in the United States for medical* supplies, British authorities rated glycerin as equal in importance to surgical instruments.

Practically all the liquid sulfonamides call for glycerin. The war has given increased emphasis also to the long-established value of glycerin itself in burn therapy and surgical treatment, as well as for wound dressings. Dressings can be changed with less discomfort to the patient when they are soaked with glycerin.

The War Production Board is urging all Americans everywhere to help save the fat from which this precious liquid is made. The meat dealer from whom you purchase food will be glad to pay the prevailing rate for the kitchen fats that your household *conserves. The pennies will buy War Stamps*—and ever pound of waste cooking fats turned in will provide enough glycerin to make one-half pound of dynamite or four 37-mm. antiaircraft shells or their equivalents in other badly needed materials. Doctors, set an example in your community: start your household saving waste kitchen fat today!—*Waste Fat Saving Committee*

Reports on Specimens for Pneumococcus Typing

In future, reports from the Division of Laboratories and Research of the New York State Department of Health on pneumococcus type differentiation will be telephoned or telegraphed only on request. While many physicians still wish the assurance provided by typing in order that specific serum therapy may, if indicated, be instituted promptly, the extensive and generally effective use of chemotherapy in the early stages of pneumonia has made supplemental treatment with serum frequently unnecessary. Hence, the procedure of reporting the results of such examinations has been revised to curtail nonessential use of telephone and telegraph services.

If type differentiation is to be undertaken, the importance of collecting sputum prior to the institution of chemotherapy cannot be overemphasized. It is essential, also, that the examination be made as soon as possible. When local approved laboratory service is not available, specimens should be sent by messenger or by mail, special delivery, to the central laboratory in Albany or to the Branch Laboratory, 339 East 25th Street, New York, New York.

DISORDERS DUE TO HEAT

	Heat Cramps	Heat Exhaustion	Heat Stroke ("Sun Stroke")
Symptoms	Conscious patient; temperature normal; pulse normal or fast; skin normal; cramping pains	Conscious patient; subnormal temperature; pulse weak and fast; *skin pale and cold*—"shock" appearance	Unconscious patient; fever (105 F. or higher); pulse very strong and very fast; skin *dry* and very *hot*
Time	Occurs in the early period of a hot spell	After some hours	Usually after second or third day of a hot spell
Age	Any age	Usually in older persons and those with *systemic* disease	More often in older persons, but *may* occur at any age
Treatment	Oral or intravenous use of sodium chloride	Warmth; rest; lay patient down flat; stimulants	Ice bath or ice pack at once
Prevention	Daily use of coated salt tablets and ample water	Daily use of salt tablets and ample water	Avoid exposure to overheating and sun for several days

—*F. J. Elias, M.D., in Minn. Med.*

wounded patients as soon after injury as possible —certainly immediately after arrival at the first casualty station. Transfusions of plasma in this zone will do more to reduce mortality from shock than any other single factor. All members of field medical units should thoroughly understand its administration.

Vasoconstrictive drugs and circulatory stimulants are of little use in the treatment of shock. Recent reports on adrenal cortical extract by the National Research Council state that it has no discernible effect on traumatic or burn shock in man. Bandaging of limbs does no good unless required locally for wounds.

Hospital Treatment of Wounds

Wounds given emergency sulfonamide treatment are usually more or less filled with caked sulfonamide powder when the patient is received in hospital. While they are not sterile and while there may be some necrosis or sloughing, there is rarely any spreading infection or fever. It has been found inadvisable to try to remove this sulfonamide. The wound area should be thoroughly cleaned, the wound irrigated with normal saline solution, and loose and obviously devitalized tissue cut away with scissors. No attempt is made at radical débridement. Reports from the Pacific combat areas state that the local use of sulfonamides plus nonsuture of wounds at first dressing have made radical wound débridement unnecessary. Those treated conservatively may be closed later by secondary suture whereas the others require later skin graft and plastic operations.

On the other hand, recent reports from the Middle East and North African combat areas have stated that wounds packed with sulfanilamide did no better than those without it and that more radical débridement and prophylactic use of antigas serum is necessary to prevent gas gangrene. From what I saw of the efficacy of the local use of sulfonamides in preventing wound infection at Pearl Harbor, I cannot agree that wounds do as well without as with sulfonamide locally. These reports do, however, emphasize recent warnings that the local use of sulfonamides is not a substitute for adequate surgery and that their use alone will not necessarily prevent gas gangrene or other wound infection from developing in deep wounds. For example, wounds caused by fragments of aerial bombs often have a small wound of entrance and extensive damage beneath. These deep wounds must be thoroughly opened, débrided, dusted with sulfonamide powder, and left open for at least three days.

With this treatment, the wounds are relatively painless and become clean in quite a short time.

Specific wound treatment in hospitals may be summarized by anatomic regions:

Head.—If sulfanilamide and sterile dressing were used in the emergency treatment of the wound, operation may be delayed as much as forty-eight hours after injury and the wound still treated as a fresh wound. The most important part of the operation is a thorough cleansing and débridement of the wound tract in the brain. This may contain hair, dirt, grass, and bone fragments. Damaged brain tissue and blood clots are removed by suction and all foreign material carefully washed or picked from the wound. It is then gently irrigated with large quantities of sterile saline solution, all bleeding controlled, the wound tract filled with sulfanilamide powder, and the external wound closed. Sulfanilamide is most effective for open wounds of the head. Symptoms of cerebral irritation, characterized by Jacksonian seizures, have followed the insertion of sulfathiazole and sulfadiazine in brain wounds. The missile should be removed if it is reasonably accessible, but if not, it should be left alone.

In head wounds operated upon more than forty-eight hours after injury, the wound tract should be cleaned and débrided as just described, the entire wound filled up to the skin with powdered sulfanilamide, and the tract loosely packed with sterile vaseline gauze or gauze strips surrounded by rubber tissue.

Chest.—Wounds of the chest vary considerably. Through-and-through bullet wounds may cause practically no symptoms, the bullet passing through the chest and leaving only small wounds of entrance and exit. Small shell fragments may traverse the lung and lodge in the chest wall of the opposite side. Patients with shell fragments in the lung may spit blood for a day or two and have no other symptoms. Varying degrees of hemothorax or hemopneumothorax are frequent. These patients usually run a fever, with a temperature of 101 or 102 F., perhaps 104 F., but they rarely develop infection and should be treated conservatively even though empyema may seem to be developing. Aspiration is not done except for respiratory embarrassment or for diagnostic purposes. In all our cases, the temperatures gradually fell to normal as the blood was absorbed. No empyema developed.

In case the wound is large, it should be rapidly cleaned, débrided as necessary, easily accessible foreign bodies should be removed, and the blood should be sucked from the pleural cavity if possible. Sulfonamide powder is then freely sprinkled or sprayed in the pleural cavity and the wound closed tightly.

Abdomen.—If there is doubt of intra-abdominal injury, it is better to do an exploratory lapar-

Because of their importance, emergency treatment of wounds may best be summarized by regions:

Head.—The majority of penetrating wounds of the head, although not immediately fatal, will result in death unless the wounds are properly treated from the beginning. All wounds of the scalp should be considered as serious. Even without associated fracture, these wounds are dangerous because of possible infection. Final suture and closing of scalp wounds should be done only in a properly equipped operating room where associated skull fracture or brain injury can be properly treated if present. If the circumstances are such that the patient cannot be transported within a reasonable time to a place where complete operating facilities are available, then as thorough a surface operation as possible may be done in the field dressing station. While this leads to primary healing of the scalp wound without treatment of the possibly coexisting skull fracture or brain injury, these can be safely treated later if the scalp wound has healed. There is less danger of infection if the scalp wound is not left open indefinitely.

Wounds of the face are an exception to the rule against primary suture. They are usually not deep, can be easily cleaned, and may be sutured without tension. Because of the excellent blood supply, primary healing usually results. Suture is especially recommended for wounds of the mouth. These frequently give excellent results from primary wound suture. In case of wounds of the upper eyelid, it is better, in addition to suturing the wound itself, to suture the margins of the upper and lower lids together with a few interrupted sutures to prevent lid contracture until the patient can be properly treated by a plastic surgeon. The technic is mechanical cleansing, freely sprinkling or spraying with sulfonamide powder, preferably suture with fine, alloy-steel wire, and applying a pressure dressing.

Chest.—These wounds permit air to rush in and out of the pleural cavity, cause marked shock and death, and must be promptly closed if the patient is to live. They may be closed with a large pad of gauze from the first aid packet, though moist gauze is better. If neither of these is available, the wound must be quickly closed with anything obtainable, the man's shirt, an ordinary thread and needle, etc.

Cutaneous emphysema is frequently noted in areas near the thoracic wound where fine crepitus may be detected. This is comparatively unimportant, for the air usually originates from outside the lung.

Emphysema in the region of the neck indicates that gas bubbles have penetrated into the mediastinum where they induce dyspnea, circulatory disturbances, and early death unless relief is given. Puncture is of no avail in these cases and only an extensive incision in the neck will adequately relieve the condition.

The outlook is more favorable if the air has escaped from the lungs and gathered in the pleural area. In this case, tension needs to be watched for immediate treatment if necessary. Too much tension is characterized by intense dyspnea and tense auxiliary respiratory muscles. The patient seeks relief by throwing his arms about. Only a small opening, a small puncture, is required to relieve this condition. Permanent drainage may be obtained by leaving the puncture-needle in position for twelve to twenty-four hours or longer. Thoracotomy may later become necessary but is preferably not attempted in the field.

In treating chest wounds, care must be exercised not to induce an open pneumothorax by injuring the parietal pleura. Simply cleanse carefully and apply a sterile dressing. Should pressure rise rapidly in a closed pneumothorax, air may be aspirated from the pleural cavity by simple puncture in the absence of a pneumothorax apparatus. Removal of foreign bodies should not be attempted until the patient reaches a hospital. Both British and American reports emphasize the necessity for conservative front line thoracic surgery.

An open pneumothorax should be converted to a closed pneumothorax at once. Difficulties arise when an open pneumothorax is first discovered upon change of dressings if no preparations have been made to meet this possibility. A wounded man who is able to breathe adequately in a watertight, well-adjusted bandage may die during the change of dressing.

Abdomen.—Patients with abdominal wounds require early operation or they will develop a fatal peritonitis. The wounds should be freely sprinkled with powdered sulfonamide and the patient evacuated to hospital as soon as possible. Too much time should not be wasted trying to overcome shock before evacuation. If it is necessary to operate on such cases in the field, they should preferably not be evacuated for at least four days postoperatively.

Treatment of Shock

Shock is the number one factor common to all war casualties. Treatment should start before its onset. Waiting for the clinical picture to develop before instituting treatment invites disaster.

The best field preventive of shock is blood plasma. It should be given to all seriously

cases in which the patient is in good condition and when adequate operative facilities are available, amputation with flap and primary suture is perhaps justified. The vast majority of such patients, however, are received under adverse circumstances. In them, a guillotine type of operation is usually advisable, all structures being cut across at the same level and the wound treated like any other large open wound. Later, an attempt must be made to cover the bone end with soft parts, or reamputation should even be done if necessary.

Skin Grafts.—The use of sulfonamides alone does not necessarily clean up a granulating wound surface for skin graft. Reports from the southwest Pacific state that the best results are obtained by sprinkling the wound with powdered sulfanilamide, covering this with gauze saturated with 1:500 solution of azochloramid in glyceryl triacetate, covering this, in turn, with gauze dressings saturated with normal saline solution, and bandaging with an elastic pressure bandage.

The dressing is kept moist with saline solution injected into the dressing through catheters. Wounded extremities should be elevated. This dressing is changed once a day. After forty-eight hours, the granulating surface is usually clean, firm, and red. Third-degree burns should be grafted as soon as they are uninfected, usually four to six weeks after injury. Paper-thin Theirsch or split-thickness grafts are superior to pinch grafts, healing being more rapid and complete and the end results better.

Anesthesia.—Spinal anesthesia is poorly tolerated by severely wounded patients. Local anesthesia may be employed if adequate for the occasion. Intravenous anesthesia is chiefly used for short procedures or to supplement local anesthesia. It is usually preferable in chest wounds, but patients with abdominal wounds do not take it well. Pentothal has been quite satisfactory. The majority of our patients in the field are given open drop ether unless an expert anesthetist is available. This is suitable for all casualties except those who have chest wounds. Furthermore, it can be successfully given by comparatively inexperienced anesthetists.

Gas gangrene has been infrequent in the present war. Using the sulfa drugs and leaving the wound open at the time of the first dressing have been considered chiefly responsible for this decrease, though the fact that but little fighting has occurred in well-cultivated agricultural areas since our entry into the war undoubtedly has some bearing.

Early diagnosis is extremely important and is based on the following three early symptoms occurring twenty-four hours or more after injury: (1) watery, brown discharge, (2) brawny discoloration about the wound edges, and (3) typical "dead rat" or garlic-like odor that is always present.

A wound showing these three early symptoms must be immediately and widely opened without waiting for laboratory report. It must be radically débrided, freely sprinkled with sulfonamide powder, and left open. Antigas serum should also be used, the first dose three times the ordinary dose. The serum should be given every four to eight hours as indicated.

Burns

Burns have been one of the most serious types of wounds during the present war and are much more common than they were in the first World War. Under conditions of modern warfare, they comprise some 60 per cent of casualties.

The most important and immediately imperative treatment of burns is to allay pain and combat shock. Morphine and blood plasma are the prime factors in treatment. Local treatment may be applied simultaneously, or it may wait. Plasma has been almost a specific in these cases.

The amount of plasma to be given varies, of course, with the condition of shock, area of burn, etc. As with wounds, at least 500 cc. should be given to severely burned patients as soon as possible. The worst cases need more. Plasma must be given rapidly, 500 cc. in five minutes if possible, to the patient in a critical condition. It should not be allowed to flow drop by drop. Syringe injection may be used. A good practical rule for twenty-four-hour administration of plasma at hospital or in the field is that used by the Navy: (1) 10 per cent of body surface burned, 1,000 cc., 20 per cent of body surface burned, 2,000 cc., etc.; (2) always give in divided doses; (3) if hematocrit determination can be done, give 100 cc. of plasma for each point above 50 per cent cells.

Following plasma, normal saline solution with 5 to 10 per cent glucose or 1.8 per cent sodium lactate solution may be given intravenously if necessary for fluid intake but should not exceed the volume of plasma given in any one twenty-four-hour period except when there is severe hemoconcentration, with hematocrit about 70 per cent cells.

Because of the condition of the skin, edema, etc., it may be extremely difficult to find a vein for plasma injection. At Pearl Harbor, it was necessary to use veins anywhere on the body for this purpose. The femoral vein is nearly always available and can be easily reached by introducing the needle at right angles to the skin

otomy than to wait until the diagnosis is certain. A conscientious effort must be made to repair these wounds, for recovery often occurs in an apparently hopeless case.

Reports from the Pacific combat area describing serious damage done by tiny pieces of metal penetrating the abdomen have emphasized the necessity of careful study of every wound of the abdomen, no matter how insignificant it may seem.

The abdominal viscera should be thoroughly examined regardless of the location of the external wound. Resection should not be done unless the intestinal blood supply is inadequate. Eight to 10 Gm. of powdered sulfonamide should be scattered through the abdominal cavity and the wound closed without drainage. Drainage is rarely indicated and may do more harm than good.

Patients with perforation of the large gut do not do so well as those having perforations of the stomach and small gut because of complicating wound infection or fistula formation. It is probably better not to close the skin and subcutaneous tissues in these cases.

Extremities.—Wounds of the extremities constitute more than two-thirds of hospital admissions of war casualties.

The presence of metal fragments in the tissues is perhaps the most frequent surgical condition encountered. These fragments may number hundreds. Most of them give no trouble and should be left alone unless readily accessible, being removed only when they lie in joints or cause symptoms. It is sometimes necessary to remove them for psychologic reasons. Wounds of joints do not do so well as wounds of the soft tissues. With them, as little surgery as possible should be done. A sulfonamide suspension should be injected in the wound and a cast applied.

Secondary hemorrhage is a constant danger in battle casualties. Metal fragments which produce relatively small wounds may partially sever arteries and cause large pulsating hematomas with constant danger of massive hemorrhage. The only safe way of treating a pulsating hematoma is by ligation of the involved artery above and below the injury and by division of the vessel. The accompanying vein is also usually ligated. The collateral circulation is good, and complications do not occur following the double ligation. Attempt at arterial suture is not recommended. The sac is not excised but is scraped with gauze, washed clean, sprayed with sulfonamide powder, and then obliterated with a few interrupted sutures.

Fractures are usually compound. These are treated in the same manner as wounds of the soft tissues and the limb is put up in plaster if it is available, traction being incorporated if necessary.

The sulfanilamide-Orr-Trueta plaster cast treatment for extensive wounds of the extremities, with or without associated fracture, was used for all such wounds at Pearl Harbor, and the excellent results obtained there have been confirmed in other combat areas. Plaster immobilization of extremities after severe wounds, with or without fracture, very definitely relieves pain and promotes healing. With this treatment, patients can be transported long distances in comparative comfort, without change of dressings, while their wounds improve.

In applying this treatment, the wound is first treated as has been described. It is preferable for the layer of gauze dressing next to the surface of the wound to be treated with vaseline or some other lubricant. Then, if the blood supply of the limb is adequate, an accurately fitting plaster cast is applied, padding being placed only over bony prominences. No window is left over the wound because it promotes herniation of tissue. Skeletal traction may be incorporated if necessary. In the absence of complications, which are rare if the wound has been properly handled, the cast is preferably not removed for three weeks after application, even though a terrific odor develops. This frequently occurs with open wounds, but it is due to discharging wound secretion beneath the cast and is not a sign of serious infection.

Patients with infection whose wounds are dressed frequently, with consequent movement of the affected part, do not do so well as those whose soiled dressings are left in place in the plaster. Frequent treatments, while occasionally required, cause unnecessary discomfort to the patient and increase severity of the infection. Plaster cast with infrequent dressings gives better results than hot soaks or other forms of frequent local treatment.

The war has produced a considerable increase in fractures of the os calcis among naval personnel. Most of these casualties are now the result of the explosion of torpedoes or bombs below decks, which causes a sudden and forcible buckling upward of the ship's deck and is likely to injure a man who may be standing on the deck. These fractures are frequently bilateral, as the man's weight is usually rather evenly distributed on both feet at the time of impact. The os calcis of one foot, however, may be more comminuted or compressed than the other.

Amputation.—Patients may be received who have had a traumatic amputation or in whom the bone has been so severely damaged that immediate amputation is necessary. In selected

Council has re-emphasized the imperative need of plasma, followed by whole blood in the stage of anemia. The efficacy of sulfanilamide or sulfadiazine by mouth or intravenously has also been re-emphasized, together with adequate fluid intake to protect the kidneys.

A point specially emphasized is the critical judgment required regarding the administration of morphine in cases presenting symptoms of anoxia, particularly hot-fume lung injuries. Under these circumstances, it is considered that the dose of morphine should not exceed 1/4 grain.*

U.S. STRETCHER BEARERS TOUGH, HEROIC, TENDER

NORTHERN TUNISIA (By Wireless).—I hope somebody in this war writes a book about the medics at the front. I don't mean the hospitals so much as the units that are actually attached to troops and work on the battlefields under fire.

They are a noble breed. They and the telephone linemen deserve more praise than I have words for. Their job is deadly, and it never ends. Just in one battalion several of the battlefield medics have been killed and a number decorated.

But noble as it is it seems to me, and to the doctors themselves, our battlefield medical system isn't all it should be. There aren't enough stretcher bearers in an emergency, and in a recent battle at which I was present some of our wounded lay out as long as twenty hours before being brought in.

The work of the medics comes in peaks. If they had enough stretcher bearers for all emergencies there would be thousands of men sitting around most of the time with nothing to do. Yet when an emergency does come and there are not enough it's an awful thing.

Wounded men had a rough time of it in this rocky, hilly country of northern Tunisia. It is hard enough to walk when you aren't carrying anything, but when two or four men are lugging 200 pounds on a stretcher it is almost impossible to keep on their feet. I have seen litter bearers struggling down a rocky hillside with their heavy burden when one of them would slip or stumble on a rock and fall down and the whole litter would go down, giving the wounded man a bad shaking up.

Litter bearers sometimes had to carry wounded men five miles or more over this rugged country. A bearer is just about done in by the time he does that, yet in battle he has to start right back again. And somehow, even though it gets to be just a miserably tough job, I've noticed that they manage to keep their sympathetic feeling for the wounded.

We've heard stories about the Germans shooting up ambulances and bombing hospitals and I personally know of instances where those stories are true. But there are also stories of just the opposite nature. Many of our officers tell me the Germans have fought a pretty clean war in Tunisia. They do have scores of crafty, brutal little tricks that we don't have, but as for their observance of the broader ethics of war, our side has no complaint.

One battalion surgeon told me of running his ambulance out onto a battlefield under heavy artillery fire, whereupon the Germans stopped shelling and stayed stopped while he evacuated the dead and wounded for eight hours.

I've heard other stories where our ambulances got past German machine-gun nests without knowing it until the Germans came out and stopped them and, seeing they had wounded, waved them on. And as far as our doctors know, the German doctors give our captured wounded good medical care—as we do theirs also, of course.

In the last war nerve cases were called "shell shock." In this war they're called "anxiety neurosis." About 50 per cent of our neurosis cases are recoverable, and even return to fighting units.

A large proportion of these cases are brought about by complete fatigue, by fighting day and night on end with little sleep and little to eat.

Surgeons sometimes spot neurosis cases that they suspect of being faked in order to get out of the front lines. Their system is to put these men on stretcher-bearer duty—a hard, thankless, dangerous task. If they are faking they get well quickly and ask to be returned to their regular outfits.

In the front lines you get so used to the constant boom of artillery that you stop jumping every time a big gun goes off. If you didn't you'd look like somebody with St. Vitus' Dance. However, there's another reaction—you get irritated. You get irritated in the same way you lose patience with a baby that cries all day or a dog that barks all night. The damn noise just never ends. There's hardly a second of the day when the guns aren't rolling or those ghostly shells rustling through the air.

Finally you get so bored with its consistency that you feel like jumping up in a huff and yelling: "Oh, for God's sake, stop it!"—*Ernie Pyle. Reprinted by courtesy of the New York World-Telegram, Copyright 1943.*

SOFTENED BY EXPERIENCE

The late Dr. James W. Leech did many tonsillectomies in his day. When he was somewhere around 50 years of age he had to have his own tonsils removed. While convalescing in the hospital he asked to have the head operating nurse sent to his room. He said to her, "Miss Potter, I wish hereafter to make a change in my operating technic."

"Yes, Dr. Leech."

"From now on when you set out my instruments please see that there is a large sterile handkerchief on the table, for when it comes over me how that poor patient's throat is going to feel in a few days I am going to burst into tears."—*Rhode Island M. J.*

1½ inches below the midpoint of Pouparts ligament and medial to the palpable pulsating femoral artery.

A point not generally appreciated is that, in emergency due to absence of available peripheral veins, intravenous medication of blood plasma or citrated whole blood can be administered through the corpus cavernosum of the penis. In occasional cases, this could easily be a lifesaving procedure. Slightly more pressure is needed than that required for ordinary intravenous infusions, but the rate of flow may be as rapid there as elsewhere. This method is not recommended for other solutions because of the risk of chronic cavernositis.

Human serum albumin may be used in emergency treatment of shock in place of plasma. Although the indications for its use are the same, it is not a substitute for plasma. While early administration will prevent the fall of blood pressure associated with decreased blood volume in shock, the value of serum albumin exists chiefly in certain military situations in which storage or transportation space is at a minimum. Its use in these situations should be mainly as an emergency measure. Since it is extremely hypertonic and draws upon tissue fluid to increase the blood volume, considerably greater clinical judgment is required for its use than for the use of plasma. The written precautions included in every package of serum albumin should be constantly borne in mind. Dehydrated patients must receive adequate fluids parenterally. Serum albumin is contraindicated in cardiac degeneration.

Local treatment of burns continues to be in a state of flux. Unfortunately, no standard local treatment can be recommended, and the individual physician must be guided by his own experience, judgment, or preference, and by the remedies available.

Burns have recently been successfully treated with double-strength normal saline solution locally or in a tub. Burned areas covered with heavy fuel oil may be cleaned by gently wiping them with absorbent cotton soaked in a purified mineral oil such as Nujol. This leaves a thin oily film which is more readily removed. Several detergents which are easily obtained commercially are also excellent for this purpose. These are Drene, Dreft, and Orvus. They are all used in 5 per cent solution and remove practically all oil.

The Subcommittee on Burns of the National Research Council has condemned the use of tannic acid in any form for the first aid treatment of burns and has discredited its use for the definitive treatment of third-degree burns because the eschar tends to lock in infections, to devitalize tissue, and to preclude the use of any other form of treatment. Serious toxic reactions, principally of the liver, have been reported where delayed or incomplete tanning permitted absorption of much tannic acid.

At Pearl Harbor, we used powdered sulfanilamide, 0.8 Gm. in 100 cc. of mineral oil on fresh burns, and powdered sulfanilamide or powdered sulfadiazine covered with compresses wet with normal saline or aqueous solution of azochloramid on infected burns, both with good results. After the raid of December 7, 1941, we used the sulfadiazine in triethanolamine spray on a few cases. Although this was satisfactory, we felt that the time and individual attention required preclude its use when any great number of severely burned patients are to be treated.

Recent reports from the Pacific combat areas state that burns were satisfactorily treated by applying dressings of fine mesh gauze impregnated with 6 per cent sulfanilamide in equal parts of cold cream and lanolin. Several layers of sterile gauze are applied over this, followed by cotton elastic compression bandages. Best results with infected burns were obtained from wet dressings of 2 per cent acetic acid.

Recently, the sodium salts of sulfathiazole and sulfadiazine have been successfully used by Fox and Tamarind in the secondary local treatment of extensive second- and third-degree burns, beginning about one week after injury. Fine mesh gauze impregnated with a 10 per cent suspension of sodium sulfathiazole in petrolatum is applied to burned surfaces and changed every two or three days as indicated. The granulating surfaces gradually presented a normal appearance and one patient was successfully skin grafted with paper-thin Theirsch grafts about six weeks after injury, indicating that the granulating surfaces were surgically clean.

The National Research Council, however, has now recommended against the local use of the sulfa drugs on burns, stating that they are of no value and appear to increase the rate of infection. They also state that aquaphor bases have been found to be not a desirable type of application.

Largely based on a study of the clinical material afforded by burned patients at the recent Cocoanut Grove fire in Boston, the National Research Council now recommends simple boric ointment or vaseline dressings with fine mesh sterile gauze and a smooth, even, compression bandage as local treatment for burns. Stockinette, or some form of elastic bandage, is more effective than a roller bandage. This should be covered with a thick layer of gauze, absorbent cotton, cotton waste, or cellulose. The

injunction to "stop worrying," which so often merely serves to send the patient out in a hectic search for a more understanding person. Unfortunately, the latter is apt to be a rapacious quack who, with the intonations of a prophet, gives the patient the consolation and sympathy that he so genuinely seeks and needs.

The treatment of all emotionally ill people is most efficacious in the setting of a warm and friendly relationship with another individual. All psychotherapy is, after a fashion, an interpersonal relationship.[1] The relationship may not be recognized by the patient or even by the therapist, but the extent and direction of this relationship determine the efficacy of treatment.

Any physician who has tried to treat emotionally ill people, however, will appreciate the fact that this task is an ambitious one and requires time and perseverance. Inevitably the patient directs the same kind of unreasonable attitudes toward the psychotherapist that he has displayed in all his previous relationships. The long period of conditioning that makes the individual's character structure a part of himself cannot be argued away by an appeal to reason. The patient is usually unaware of why he reacts the way he does, and he develops attitudes of hostility, disappointment, and rejection toward the physician in spite of his better judgment.

The relationship that the patient establishes with the physician is motivated by a deep desire to fulfill those biologic longings that are a heritage of every human being. Inevitably, however, the physician becomes the target of the patient's neurotic goals and compulsions. The patient may, for instance, submit himself, render himself defenseless, or become a martyr. He may struggle with a need to victimize himself so that he can criticize the physician. He may identify himself with the physician, or tear him down in fantasy, or verbally, or by actual aggressive acts. He may strive to cash in on submissiveness by toadying to the physician while at the same time he burns inwardly with indignation. He may be paralyzed in his relationship and take a thousand precautions before he expresses himself so as not to offend. He may compete with the physician or try to outshine him. He may strive to crush whatever atom of individuality he has left if he feels the physician will be good to him and protect him. He may resent intrusion into his private ambitions and fantasies and express disguised or open hostility. These and countless other attitudes will unfold themselves as the therapeutic process proceeds.

The attitudes are important clues to the general character organization, and when they are brought to the attention of the patient they permit him to understand his problems while actually re-experiencing them. This enables him to work through the dynamics of his reaction patterns in his relationship with the physician.[2] Under these circumstances, the various defense reactions and resistances which are directed against inner fears and strivings become apparent to the patient not as theories but as real experiences, and he is gradually enabled to gain insight into his unconscious motivations.

Unwholesome reactions are bound to occur from time to time, and unless they are analyzed they may interfere with treatment. One of these is a clinging, dependent attitude toward the physician, who is overvalued as the embodiment of all that is good and strong and noble in the universe. This sort of relationship is rooted in an intense feeling of helplessness, escape from which is sought by seeking protection in a deity or dictator, a shrine or cult, that can in some magical way lead the person into paths of health, glory, or accomplishment. The so-called "faith cure" is based upon a relationship of this nature. The ability of the person to build up the priest, shrine, physician, or charlatan to his magical expectations and to ally himself with the object of his creation restores his security and self-esteem.

The aim in treating the individual who operates on the basis of magical expectancy is to convince him that he has rights and abilities of his own, that he is capable of functioning without the aid or sanction of a stronger person. This is accomplished only against great resistance, for the patient acts as if he has an amputated self and needs to replace it by fastening himself parasitically to a more powerful host. He will offer great resistance to the suggestion that he enter more actively into the therapeutic relationship and try to do things for himself. This is because he has little confidence in his own actions or ideas. He will furthermore regard failure of the physician to live up to his expectations as evidence of ill-will toward himself, and he will be tempted to interrupt treatment and go out in quest of greater and more powerful gods. It takes much patience to kindle the spark of independency that remains into a flame that lights the way to freedom and self-assertiveness.

Another unfavorable form of relationship is that of fear of the physician as a potentially destructive or malevolent being who threatens to injure or to engulf the patient. The nucleus of this attitude is a hostile image of the parent that is later displaced on all authoritative individuals. The basic attitude of fear may be disguised by secondary defensive devices, such as aloofness and detachment toward the physician, or defiance, skepticism, and indifference. There is a great resistance to the revelation of

RECENT TRENDS IN PSYCHOTHERAPY*

LEWIS R. WOLBERG, M.D., Kings Park, New York

MENTAL health involves a harmonious interaction of intellect, of emotion and behavior, of conscious and unconscious motives, of environmental and personal standards, of internal drives and reality pressures. The person with integrated attitudes is capable of functioning smoothly in his contacts with the world. The emotionally unbalanced individual, on the other hand, is incapable of making adjustments essential to the gratification of his impulses and goals. He is driven by anxiety to compromise his fundamental needs in favor of neurotic defense mechanisms that serve a vicarious safety function.

The seeds of mental health develop in the soil of the mother-child relationship during the first years of life. There is a biologic reason for this. The human infant is the most helpless of all creatures and is dependent upon his mother for every kind of service. How well his pleasure strivings are gratified, how secure he feels in his relationship with his parent will determine his later attitudes toward himself, toward the world, and toward other individuals. If the mother is a loving, bountiful mother, the child's relationships with others will in all probability be based upon love and expectancy. If the mother is a rejecting mother or an excessively disciplinary mother, there more likely will develop attitudes of disappointment and fear.

Genetic and constitutional elements undoubtedly enter into the molding of a child's personality. Any observer of infants knows that there are differences among children, particularly in the gradation of emotional endowment. We may expect, therefore, that different children will react with varying intensities to parental deprivation and frustration. This does not alter the fundamental rule that all children will show catastrophic reactions to a withholding of maternal love.

The core of a person's attitudes toward the world is built from his experiences with the world. When these experiences prove to him that the world is a menacing place in which to live, defensive reactions are elaborated to preserve the integrity of the self against danger. These reaction tendencies are imbedded in the character structure which regulates relations with the world and with other individuals.

While many character traits protect the person against real or fancied dangers, they often disable him in his adjustment to life. For instance, when parents are domineering, hostile, or excessively disciplinary the child may acquire an inordinate suspicion of other persons, a fear that he is unloved and that he cannot depend upon anyone except himself. He may strive to protect and isolate himself from danger by an entrenched attitude toward life whereby he detaches himself from other persons, becomes aloof, obstinate, and suspicious. At the same time he may strive to make himself secure by a compulsive drive for power, prestige, or possessions. These drives have a passionate quality, for they serve as reactions against helplessness and loss of self-esteem. Yet they often bring the person into conflict with others and frustrate the gratification of his instincts and cravings.

When the character structure becomes incapable of adjusting the individual to his inner strivings and to environmental demands, the ego retreats to a secondary line of defense in neurotic behavior and symptom formation. It is important to remember, however, that associated with every neurosis is a defective character structure which eventually victimizes the person and puts him at the mercy of compulsive drives. This concept is important in therapy, for unless subversive character traits are undermined, neurotic symptoms will either resist treatment or will vanish temporarily only to return later in a slightly disguised form.

Injured tissues possess within their substance a spontaneous urge to mend themselves. In emotional illness, too, the individual has a biologic striving to heal his damaged relationships with his fellow creatures. Every physician is acquainted with the psychoneurotic who drifts from doctor to doctor, from clinic to clinic in never-ending trek, ceaselessly seeking solace for his fancied ailments. What the patient seems to want is a magic pill that can miraculously dissolve his woes, but deeply, perhaps unconsciously, there is a frenzied attempt to find a human being who is kindly and understanding and with whom he can establish a congenial relationship. At the root of his desire to use people as outlets for his compulsive neurotic drives, to cling to them or to dominate them, is a healthy tendril of wanting companionship and love. Cognizance of this may make the practitioner less impatient with the histrionics of the neurotic and less likely to dismiss him with the

patient is the extent to which he is able to reorient himself in his relationships to people, evidenced by his acceptance of the physician as a human being, neither as a demigod nor as a demon. Because of a diseased character structure, the attitudes of the neurotic and psychotic toward others are disturbed and any relationship that he is able to establish is an unstable one threatened constantly by neurotic needs and compulsive drives. It is a prolonged process that breaks the vicious chain of magical expectancy, frustration, and fear of injury which tincture the attitudes of the emotionally ill person.

Interpretation by the physician of the defense reactions and resistances and of the progress of the relationship is of vital importance to the achievement of insight. A kindly and tolerant attitude toward the patient is indispensable, and the physician must be aware of his own personal conflicts in order not to be threatened by the expressed hostility of the patient and in order to avoid using the patient as an object for his own interpersonal problems. It is essential also to evade the god-like mantle of omnipotence that the compulsively dependent patient strives to throw over the doctor's shoulders in his quest for a faith cure.

The goal of interpersonal therapy is a rehabilitation of the individual as a functioning unit in society and the development of attitudes related to the world, to himself, and to other individuals capable of satisfying rather than hampering his fundamental needs.

SIX RULES FOR HEALTH PROTECTION OF WORKERS

In a May Day statement, New York City Health Commissioner Ernest L. Stebbins laid down six minimum essentials for protecting the health of the young workers now entering employment. These new workers include those 16 and 17 years old who are leaving school for full-time employment and those from 14 years up who are taking part-time jobs outside of school hours.

"Good health care for the unprecedented numbers of teen-age youngsters who are now taking jobs," said Commissioner Stebbins, "is a matter of urgent concern for parents and the whole community. The following six points should be borne in mind:

"First is the need for *proper and sufficient food.* Too much stress cannot be placed upon the importance of choosing the right kind of meals for the working adolescent. He needs three substantial meals a day which supply an adequate amount of all the food elements required to keep the body in good condition.

"Second, *adequate sleep* is most necessary. Left to his own device the teen-age boy or girl who finds that he has money in his pocket is prone to develop the habit of prolonged night entertainment, which will deprive him of adequate rest and will undermine his health. The test of adequate sleep is whether the youngster awakes well rested in the morning.

"Third is *recreation appropriate to the young person's needs.* This is especially important for boys and girls who are making a sudden transition from school life with its varied activities to a confining eight-hour day in industry.

"Fourth is the need for *periodic dental and medical examination.* Tuberculosis is a serious health problem for adolescents. Often children have the infection in an inactive form and an additional strain during the teen years causes the infection to flare into active disease. Pre-employment examinations are not sufficient. There is need for periodic medical and dental follow-up.

"Fifth is *avoidance of overfatigue and following the rules of safety.* Strict limitation of hours of work in accordance with the New York State laws is most important. It is equally essential that the job selected should be suitable to the individual youth. Rest periods, if only of five or ten minutes during the day, add to the young worker's efficiency.

"Sixth, and above all, every youngster should be given the opportunity to lead as *normal a family life* as possible."

Commissioner Stebbins explained that "the Health Department working papers clinics, which give physical check-ups to children and young people wishing to secure employment, examined in 1942 a total of 109,957 children and young people, as against only 45,339 in 1940. The number is increasing, and during the first three months of 1943 a total of 32,420 minors under 18 were examined by the Department's working papers clinics. Young persons now entering employment are under great strain, particularly those who carry a combination load of both school duties and work. Many of them are expected to handle jobs previously performed by older workers, and their health must be carefully watched."

The health of the adolescent youth is of such vital importance to the country that President Roosevelt stressed this in his Child Health Day proclamation, and urged "special measures in behalf of those boys and girls of high school age who are combining school with part-time jobs, working during vacation, or entering full-time employment, in order that their safety, health, and normal growth may be fully assured."

inner fantasies and hopes, for to reveal them is to put oneself at the mercy of another dangerous person. The goal in life is to maintain one's integrity and intactness by warding off impacts from the outer world and by maintaining a chasm between oneself and others. Treatment in this type of patient proceeds only when he realizes that the physician does not desire to punish him for his inner strivings and demands but is benevolently neutral toward them. The relationship will remain shaky for a variable period of time. The patient will retreat whenever he feels that his attachment is getting too close. A "testing period" precedes his final acceptance of the physician as one who bears only good will toward him. During this period he will be torn between his desire to establish a gratifying relationship and an overpowering fear of injury. The outward manifestations of this struggle may be hostility to the physician. Children with behavior problems, for example, may attempt to provoke the therapist and to incite him into acts of aggression to prove to themselves that all human beings are alike and are not to be trusted. This "testing period" will be especially prolonged in the psychotic, and it may be many months before the patient accepts the physician as a friend.

Free communication is always essential between the physician and patient. If the latter is a child, the physician must use the language of the child. This language is play. Much that the child cannot or will not verbalize he will express in play activities. Indeed in recent years the orientation in child therapy has been around the use of play technics and materials.[3]

In the case of the psychotic it is essential for the physician to understand the symbolic language that the patient utilizes in his regression to primitive phases of his development. Much as the dream language has a function, so the language of the psychotic, albeit bizarre and seemingly incomprehensible, has a rich and vital meaning that must be understood before a treatment situation can be established. Pioneer work in this field is being carried on at the Menninger Psychiatric Hospital and at Chestnut Lodge in Baltimore, where psychotic individuals who have regressed far into a world of their own are brought back to reality by rehabilitating interpersonal relationships.[4]

Whether or not complete insight is essential for cure is difficult to say. This will depend upon our definition of insight. If by insight we mean the recovery of infantile memories, particularly traumatic sexual experiences, relating them to the existing symptoms, we may fail to attain this sort of insight even when considerable change for the better has occurred in the patient. Conversely, infantile memories may be recovered without apparent influence on the character structure. If by insight, however, we mean a changed attitude toward life, a realization that the world is neither menacing nor hostile and that people are not necessarily the purveyors of pain and destruction, then insight is an ingredient essential to personality change. This form of insight develops slowly and is often unexpressed.

The attainment of insight reflects itself in a changed attitude toward people wherein the patient feels neither threatened nor challenged to excel, wherein his expectations are neither so high that he is inevitably frustrated nor so low that he fails to permit himself to express his needs and strivings, wherein he is not excessively dependent on others nor compulsively determined to play the lone wolf, wherein his self-esteem is not forever in jeopardy, swelling and ebbing with the opinion of others, wherein he can express his instinctive longings without fear of condemnation and feel justifiably hostile without fear of injury.

The interpersonal approach to psychotherapy concerns itself primarily with character structure and only secondarily with symptoms, for the symptom picture itself is an outgrowth of a failing character function.[5] It matters little, consequently, whether we are confronted with a behavior problem in a child, a psychosomatic syndrome, a psychoneurosis, or a psychosis. In each our aim is the winning of the patient over to the realization that not all human beings are dangerous, or contemptuous, or frustrating. He must learn that he can be accepted for what he is rather than for what he does, that feelings of hostility need not result in counterhostility, that he has the right to be self-assertive and free, that he need not force himself to be "good" in order to be loved or execute rituals of conformity or obeisance toward all authoritative individuals.

Around the relationship with the physician are rebuilt attitudes shorn of neurotic fears and expectancies. Once this is achieved, compulsive drives and neurotic symptoms no longer have purpose or protective function, for they are at best incomplete substitutive gratifications and involve much compensatory suffering.

Summary

In recent years great emphasis has been laid on the psychotherapeutic potentialities of the relationship that develops between physician and patient. The psychoanalytic school was first to investigate this relationship by dissecting the transference of the analysand to the analyst. It has become increasingly apparent that what actually determines improvement or cure in the

symptomatic relief, the so-called immunity, resulting from specific therapy.

Patients sensitive to ragweed pollen show not only wide quantitative variations in the degree of sensitiveness but also important qualitative differences which must be understood to secure the best results.

In specific therapy one is seeking satisfactory clinical results without disagreeable local or dangerous systemic reactions. In some cases good results are secured with a maximum dosage of 100 protein nitrogen units or less, while in other cases 100 to 200 times this dose is needed. In general, the use of skin tests with serial dilutions of, say, 10, 100, and 1,000 units per cc. will indicate the highly, the moderately, and the less sensitive groups, and so the dangers of a general reaction in the early stages of treatment may be avoided by using such dosages. These I have outlined in Cecil's *Textbook of Medicine*.

In the later stages of treatment, general reactions seem to be due to the lack of development of a protective antibody. This occurs chiefly in those patients who are sensitive to one of the several proteins in ragweed pollen which we call "Fraction 2." Although it is a poor stimulant of the protective mechanism, it is a good reactor. In clinical practice, dangerous reactions after pollen therapy are avoided by keeping patients under observation for at least twenty to thirty minutes after an injection. If symptoms of a general reaction start, epinephrine, 1:1,000 in doses of 0.5 to 0.7 cc., is given, and the tourniquet should be promptly used.

We believe that the perennial treatment of pollen-sensitive patients—that is, monthly injections of the maximum dose—is advantageous to many, but not to all patients. All extracts of inhalant allergens, such as danders, dusts, and the like, are used when indicated in the same general and empirical way as the pollen extracts, and perennial treatment is particularly indicated on account of the continual exposure to contacts.

Symptomatic Treatment.—Very little can be done with drugs to allay the symptoms of hay fever. Sometimes atropine sulfate in doses of $^1/_{200}$ to $^1/_{500}$ grains may lessen the discharge. A spray of 0.5–1 per cent cocaine will give temporary relief but is too dangerous to prescribe. Ephedrine, $^3/_8$ grain, taken by mouth may help to reduce the edema. In sprays of 1 per cent it gives temporary relief but should be used sparingly and for a short time only, as it often produces a vasomotor rhinitis if used over a long period. In general, local nasal treatments such as carbolic acid, cauterizing agents, and packs are to be avoided, for they increase tissue irritability and reactivity and never give more than temporary relief.

Hyperplastic Rhinitis.—With this condition we must also consider sinusitis and polyposis, for they are frequently associated. Irreversible tissue changes have taken place. Many of these cases are associated with vasomotor reactions to air-borne excitants. In fact, they seem to follow longstanding vasomotor allergies and perhaps may be caused by them. From studies of these cases with Dr. Grove, our present inclination is to consider them as a special sensitization reaction to bacterial invasion, which is the primary cause but is aided and abetted by the existing vasomotor change.

Clinically speaking, infection dominates the picture ultimately. I give this brief outline of our concept of the pathogenesis because it aids in the appreciation of therapeutic procedures. These measures are: management of contributing factors; specific vaccine therapy; operative intervention; symptomatic drug therapy.

There is as yet no satisfactory evidence that vitamin deficiencies or endocrine dyscrasias either cause or predispose to the condition except in so far as general good health tends to discourage any infective process.

Whenever vasomotor allergies coexist, they must be treated as already outlined by avoidance of the cause or by specific injection, and this may be sufficient to give symptomatic relief and permit the infective process to become latent.

By way of illustration, I might cite the case of a physician with a longstanding history of frequent nasal operations, polypectomies, septal, and turbinal resections, without relief. He was found to be sensitive to casein. Symptoms promptly disappeared when he avoided milk and cheese, which he had taken freely, and no further operations have been needed for the past six years, although he still has the objective nasal and sinus tissue changes.

Foods, however, contrary to the belief of many, rarely cause trouble. Air-borne factors are common. In patients subject to frequent exacerbations of infection or in whom infection is the sole cause, one seeks for primary foci such as infected adenoids, tonsils, or teeth. If present they should receive prompt surgical attention.

The next step is to determine the type of infection. This is easier said than done, for cultural studies have shown that organisms deep in the tissues are, in at least 50 per cent of the cases, not identical with those obtained from the surface by nasal swabs or antral irrigations. Without operation, however, such surface cultures are the best available for vaccines, and from clinical observation I believe that such

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the August 1 issue and will concern "The Doctor's Bag."

Treatment of Asthma and Hay Fever

DR. HARRY GOLD: The treatment of asthma and hay fever is the subject of the conference this morning. There have been many interesting developments, as you probably know, in the field of allergy, asthma, and hay fever. The subject of allergy has to be dealt with in connection with disorders of every system of the body in relation to problems of diagnosis as well as treatment. One of the major contributors to this field is the person who is going to open the discussion this morning, Dr. Robert A. Cooke, of the Roosevelt Hospital.

DR. ROBERT A. COOKE: I have somewhat the feeling of paying a visit home when I come here to talk with you today because, as at least some of you know, I was connected with this institution for many years—going back to perhaps 1915 or 1916. There is one difference, and that has been caused by the very sudden passing of my friend, Walter Niles. His death has made, and will continue to make, a great deal of difference to this institution, to which he gave so much in the way of effort and intelligent direction.

Now, as to our conference this morning, Dr. Wheeler has given me thirty minutes in which to open this discussion on the treatment of respiratory allergies, and in order to cover the subject-matter in its most important phases in the allotted time I shall take the liberty of reading these opening remarks.

As I have outlined my talk in my own mind, it will be better to consider the treatment of hay fever first, as a natural approach to the later discussion of asthma, but it should be emphasized here that these two allergies involving the respiratory tract coexist more frequently than not, and that much of what is said about one is applicable to the other.

I have assumed that the title "hay fever" is used in a general way to include all types of nasal allergy. It simplifies matters considerably if we consider them on the basis of the pathology involved, as (1) vasomotor (an acute and completely reversible reaction), and (2) hyperplastic (a chronic and irreversible tissue change), though it must be appreciated that a vasomotor reaction also occurs in hyperplastic membranes.

Vasomotor rhinitis, or allergic coryza, is seasonal or perennial, depending on the cause. The seasonal pollen hay fever is a simple vasomotor reaction like the perennial inhalant allergies, the rare food allergies, and certain infections. In a general way we may sum up the treatment, or rather the management, of these cases under three heads: (1) avoidance of cause; (2) immunization; and (3) symptomatic medication.

Avoidance of Cause.—This, of course, presupposes accurate determination of the cause by appropriate tests. In the case of pollen, it may be avoided by moving to pollen-free areas. However, this is not always feasible on account of loss of time and the expense involved. Air filtration and conditioning of a room, the home, or the office lessen exposure and are real helps. In the case of other inhalants encountered at home, much can be accomplished by careful cleaning and renovating and the elimination of certain household articles—a pillow, a mattress, or chair, or perhaps of the family pet or the type of insecticide used. If the allergen is encountered at work, as in the case of furriers, bakers, or hostlers, a change of occupation may be required, and if in foods—which in my experience is unusual—they should be omitted from the diet. Nasal infection causing vasomotor rhinitis is, eventually, at least, associated with hyperplastic sinusitis and will be considered later.

Immunization.—This is the accepted therapy for pollen and certain inhalant allergies, and, in a way, has become standardized, as witnessed by the fact that many sufferers get relief by injections of specified graduated doses of commercial preparations, but exceptional and difficult cases are so frequent and results so uncertain that much time and labor are being spent for a better understanding of the immunologic factors involved in the reaction itself and in the

fection, and existing areas or foci of infection in the respiratory tract. The first of these has been discussed. Nutritional or other diseases must receive appropriate treatment. The question of contacts is important. Persons with chronic sinus infection should not be employed as nurses. Infected members of the family unfortunately cannot be dealt with save by advice.

But something can and should be done about areas of focal infection in these patients. Children up to 18 years of age need little attention to the sinuses if recurring infections can be controlled, and the early removal of infected tonsils and adenoids is one of the best methods of control. In those patients with lymphoid hyperplasia of the pharynx not susceptible to surgical removal we secure beneficial results by the use of x-ray therapy as originally outlined by Remer. Vaccine therapy is useful in these cases, combined, when indicated, with dust, dander, or pollen injections.

Particularly important are the infective asthmas of the older age group, those over 30 or 40 years of age. This bacterial asthma occurs not infrequently in those with atopic allergies of early life, as well as in the large and important group who have had no history of allergy before the onset of the asthma. About 15 per cent of these cases are due to primary bronchial infection. The balance have upper respiratory foci which I believe, from my observation, long antedated the onset of asthma and may therefore be considered primary.

Generally speaking, these cases, at first periodic, when left to run their natural course become chronically and persistently asthmatic, usually with exacerbations, and the patients tend over the years to grow steadily more and more incapacitated. To severe chronic asthma the term "status asthmaticus" is applied.

Let us assume that these cases have been thoroughly studied from the general medical aspects; that the patients have asthma with perhaps certain of its direct sequelae, such as emphysema, cor pulmonale, and pulmonary fibrosis; and that their atopic allergies have been, or are being, adequately handled.

Let us first consider specific treatment directed against the cause. Specific therapy is as follows: (1) removal of primary foci, (2) immunization by vaccine therapy, and (3) specific drug therapy with sulfonamide compounds.

Primary foci are found in 85 per cent of our infective asthma cases. The teeth are important in so far as they may be the origin of sinus (antrum) infection—although rarely of and by themselves—and should receive first attention. Tonsils, when infected, and, rarely, adenoids in adults, require enucleation. Sinuses, and particularly antra, are the most frequent foci in our series.

The usual pathologic change in the sinuses is hyperplastic; hence a purulent discharge is not present except in acute exacerbations and is not the criterion for operation. Though sinus disease should be diagnosed at once, we usually prefer a conservative course of vaccine therapy first. It is not often successful, but it gives opportunity to size up the patient, to build up reserve, to prove perhaps to the patient that climate, even that of Arizona, will not effect a cure, and finally to choose a more propitious time of year, late spring through early fall, for the operation.

When this treatment has been carried out in accordance with the suggestion that I made earlier, the results have been satisfactory and worth while in 80 per cent of about 300 patients whom Dr. Grove has operated on. The aftercare is important, and requires rest during the six weeks of healing after antral surgery and, when possible, for several months thereafter. There should be a convalescent home for postoperative clinic patients just as there is for tuberculosis patients.

Vaccine Therapy.—Our preference is for autogenous vaccines prepared from tissue cultures and from sputum. Prepared in a stock 1-per-cent-by-volume suspension, we begin dosage with 1:1,000 dilutions of this and increase very slowly up to and through the 0.1 per cent suspension if possible. The danger, as I see it, comes from too large dosage, which frequently induces a symptomatic asthma. I have many times seen patients in severe status asthmaticus caused by vaccine therapy.

Drug therapy with sulfonamide compounds may work well with those whose infection is caused by the pneumococcus, the hemolytic streptococcus, and the staphylococcus. Good results may be obtained with such moderate amounts as 1 or 2 Gm. a day for two or three weeks, but the results are likely to be temporary. One must watch for sensitization to the drug, which sometimes occurs in these patients. Dr. Wheeler and I were just talking about this and agree that one should not use these drugs indiscriminately because the development of a sensitization will prevent the use of them later if occasion arises—for instance, in lobar pneumonia.

Symptomatic Treatment of Asthma.—This discussion considers all cases, mild or severe, of whatever cause, atopic or infective. In acute asthma, particularly the atopic type, the bronchial obstruction seems to be due to congestion and edema of the mucous membrane similar to those seen in vasomotor rhinitis. Judging from autopsy studies of the fatal cases in chronic

autogenous vaccines are superior to stock preparations, but tissue culture vaccines are superior to surface cultures. It is unfortunate that there is no simple test to determine sensitivity in these cases of bacterial allergy. Certain it is that the usual vaccine skin test is useless. Vaccines do at times give satisfactory results in these cases. Their use and dosage will be further considered under "Asthma."

When results are not obtained by the measures just outlined, recourse must be had to sinus surgery, and I wish to make a few general comments on sinus surgery because they will be applicable in our consideration of infective asthma, and because of a general disrepute into which sinus surgery has fallen because of unsatisfactory results. But, frankly, I believe in sinus surgery because I have seen its benefits in many persistent and otherwise intractable cases.

My comments may be summarized as follows:

1. Rarely is surgery indicated in a patient under 25 years of age.

2. In patients allergic to inhalant and food substances, avoidance of or treatment with the allergen should always be practiced before and after surgical procedure.

3. The operation must be superlatively well done by one trained in surgical technic and with a thorough knowledge of the anatomy of the sinuses.

4. The object of sinus surgery is to remove infected tissue, leave the sinuses well open for drainage, and conserve as much turbinal tissue as possible. Resection of the septum is indicated only when there is interference with the approach to the ethmoid and sphenoid cells or a complete blocking of a nasal cavity.

5. The trouble with sinus surgery is that it is done in piecemeal and incomplete fashion or it is done too late.

6. The cases must be carefully selected on the basis of their physical condition. One should not expect satisfactory results in old, long-standing cases with extensive pulmonary fibrosis.

As for symptomatic treatment, there is nothing to add to that already given under vasomotor rhinitis, except that it is particularly ineffectual.

Asthma.—In considering therapy in asthma, I am referring to true asthma, not cardiac, renal, or other forms of dyspnea. I shall divide the subject into, first, atopic asthma, the type in which the cause is determinable by skin test and which, roughly speaking, includes the cases caused by air-borne substances, foods, and drugs. The second type is infective asthma. This differentiation will facilitate my discussion, but it must be understood that both types are not infrequently seen in the same person, just as vasomotor and hyperplastic rhinitis occur together. Atopic asthma corresponds both immunologically and pathologically to vasomotor rhinitis, and infective asthma is the counterpart of hyperplastic rhinitis.

Atopic Asthma.—The attack may be paroxysmal or continuous, depending entirely upon contact with the exciting agent. This is the type of asthma frequently seen in infants and usually in children and young adults, and it may continue through life, but it rarely begins after 40 years of age.

Here we will consider treatment as directed against the cause—that is, prevention of attacks by avoidance of the cause of immunization. The symptomatic treatment of asthma, both atopic and infective, will be discussed together.

The prevention of attacks by avoidance or immunization presupposes the accurate determination of all causes. Among the more difficult cases are those of children who are continuously asthmatic but not completely disabled, whose asthma is due to some allergen in the home. What was previously said concerning vasomotor rhinitis is applicable here. When contact with the allergen is unavoidable, then recourse must be had to immunization. The important point to remember is that therapy must be carried on for years, not merely weeks or months, and care must be taken against intercurrent respiratory infections, which are the forerunner of a later sinusitis and asthma.

Infective Asthma.—Infection is a cause of asthma from infancy to old age. An acute infective asthma is seen particularly in infants, children, and young adults, when it is strictly periodic. It occurs in older adults, but here it is usually the cause of an acute exacerbation in a chronic asthma. In these patients there is active upper or lower respiratory disease, or both, which, were it not for associated dyspnea, would be a rhinitis, tracheitis, or bronchitis, or a patchy or lobar pneumonia. In these patients there may be fever of greater or less degree in the early stages, which may have subsided when the asthmatic paroxysm sets in, often several days after the onset of illness. Infection may be the sole cause of asthma in the earlier age group, but more frequently it occurs in those who have asthma of atopic origin. In such instances all of the factors causing asthma, both atopic and infective, must be controlled when they are concomitantly active in any one patient.

All patients who have had asthma from infection are peculiarly susceptible to recurring infections; hence we must deal with such predisposing factors as associated atopic rhinitis and asthma, malnutrition or associated disease, contact with those who have respiratory in-

of orange peel, can be recommended, but it is disagreeable. For adults, codeine, 1/2 to 1 grain, or pantopon, 1/6 to 1/3 grain, repeated three or four times a day is of greatest use. Dosages for children are proportionately reduced. If these drugs produce vomiting at first, so much the better, for it is more effective than coughing in dislodging mucus plugs. I have myself never seen serious results from the judicious use of these drugs, or even morphine. Certainly the control of the cough is necessary. I sometimes use chloral, 15 to 30 grains. Avertin, about 70 mg. per kilogram, or ether, 4 ounces in 3 ounces of oil, by rectum, have been recommended by some, but I find little use for them in my service.

There are still other procedures. Digitalis is necessary when there are signs of heart failure, best indicated by delayed circulation time or by increased venous pressure. One should always be on the lookout for this, especially in the elderly patients, and in patients with cor pulmonale. Strophanthin, 1/100 grain intravenously, may be indicated if failure is acute.

Irrigation of an antrum and the removal of accumulations of pus from the nose by suction or irrigation help if there is a purulent infection of the upper respiratory tract. Mustard paste broadly applied to the front and back of the chest at intervals is very comforting to many patients, as well as steam inhalations, especially in those with acute respiratory infection.

Artificial fever therapy is useful in prolonged status asthmaticus. I prefer to use the standard triple typhoid vaccine intravenously, at first 0.5 cc. of a 1:100 dilution and increasing daily, perhaps to as high as 1 or 2 cc. of a 1:10 dilution —enough at least to give a temperature of 102 or 103 F. Two or three such febrile shock doses often bring welcome, though temporary, relief.

Histamine, histaminase, calcium, and potassium salts, highly regarded in some quarters, have not yielded worth-while results in our clinic. Atropine and belladonna are contraindicated drugs. Intrabronchial use of iodized oil is mentioned only to be condemned as a dangerous therapeutic agent, though useful for diagnostic purposes in selected cases.

Time does not permit discussion of several other aspects, such as prophylactic therapy, the management of psychic factors, nutrition, and climate, all of which are of importance in certain cases and are included in the efficient management of the asthmatic.

DR. GOLD: Are there any questions?

DR. C. H. WHEELER: Dr. Cooke, I am not quite clear on your notion of the role of infection in the so-called infectious asthmatics. Do you believe that the presence of infection makes individuals sensitive to extraneous allergens, or is the individual sensitive to the products of the metabolism of the bacteria he carries?

DR. COOKE: The absolute proof of the existence of an allergy to bacteria is lacking, but just as we speak in general terms of drug sensitizations today, so also do we speak of a bacterial sensitization. What is called allergy to bacterial substance is evidenced by the fact that we can induce asthmatic manifestations by the injections of minimal doses of vaccine in certain persons with infective asthma. That is particularly true when vaccines made from autogenous cultures are used, and I might add that it is the reason for the care in the use of vaccines therapeutically.

To sum up then, I believe that in these infective asthmas we are dealing with a sensitization to either the bacteria or their products.

DR. WHEELER: And so, in such individuals little or nothing is to be hoped for by attempting to remove things from their environment, such as animals or feather pillows?

DR. COOKE: That is true, unless they are shown by skin tests to be atopic persons and also sensitive to environmental factors. The two, as I said, frequently coexist.

DR. JANET TRAVELL: In connection with the treatment of hay fever, I wonder whether Dr. Cooke would tell us the distinctions between the terms "desensitization" and "immunization."

DR. COOKE: Well, when we speak of desensitization what we really mean is that we are whittling away and destroying, or removing, the reacting antibody. That, I think, would be the natural concept of the term "desensitization."

However, in the immunologic study of these cases we find that when we begin to treat hay fever patients with injections of specific antigen, a pollen extract, at least during the first three or four months the circulating sensitizing antibody is increased in the blood and not diminished, although the patient may be clinically free at the same time. There is evidently an increase of the skin-sensitizing antibody, and since that is so, it does seem to me that the term "desensitization" is an inappropriate one. We believe, although we have not been able to prove it, that through injections of allergens we are creating a kind of actual immunity which coexists with the sensitization.

DR. GOLD: Dr. Cooke, what is the basic difference between atopic and infectious allergy?

DR. COOKE: When the term "atopy" was originally coined it was meant to designate the so-called hereditary group, but it has come to be

asthma, the chief obstruction is due to blockage of the bronchi with inspissated plugs of mucus. What we are attempting to accomplish by therapy in asthma is, first, the relief of bronchial obstruction; second, the relief of oxygen deficiency; and third, the rest and comfort of the patient by all other measures available. Let us consider them in this order.

The measures to relieve bronchial obstruction are:

(*a*) Drugs. In the milder cases, those with asthma after exertion or exposure to cold, symptomatic treatment is relatively simple, and relief may be obtained by drugs alone, such as ephedrine 3/8 grain combined with amytal 3/4 grain, or phenobarbital 1/2 grain, or epinephrine 1:100 in the special vaporizer for inhalation, which is helpful if used correctly and not too often. When combined with 10 to 20 per cent glycerin, a better mist is formed, which is an advantage. If the asthma is more acute, epinephrine 1:1,000 0.3 to 0.7 cc., by injection, is effective; or epinephrine, 2 mg. in 1 cc. of peanut oil or gelatin, may be used for less pronounced but longer effect. Aminophylline, 1 1/2 to 3 grains, combined with 1/4 grain phenobarbital, is also helpful.

Recently Harkavy and his associates have recommended nicotinic acid, 50 to 100 mg. three or four times daily. I have not had extensive experience with it but have seen no striking effects except that patients get a flush like that produced by intravenous aminophylline. In occasional cases acetyl salicylic acid, 5 to 10 grains, does remarkably well, but this drug should be prescribed with caution as asthmatic sensitization to it is not infrequent and death has been caused by its use. Potassium iodide, 5 to 10 grains, three times a day, should always be tried, of course, except in those who are sensitive to iodine. Occasionally it works marvels. I have seen no great virtue in the intravenous use of sodium iodide. Antipyrine is another drug to remember, as it gives relief when administered in doses of 5 to 10 grains.

In the asthmatic paroxysm of children, syrup of ipecac, 1/2 to 1 teaspoonful, is given to produce emesis. The act of vomiting is often more helpful than coughing in removing mucus from the bronchi. Stramonium smoke by inhalation, used as a powder or cigarette, is also helpful for the milder cases.

In the severe paroxysms and in cases of status asthmaticus, in addition to epinephrine in its various forms, aminophylline, 7 1/2 grains intravenously once a day or even more frequently, is useful. It is a great help when patients in severe paroxysm can be hospitalized, for, particularly in the younger group, an environmental factor such as dust may be important and is thus avoided. In this case the paroxysm automatically subsides in about forty-eight hours. During the pollen season air filters or conditioners are also available in most hospitals.

(*b*) Dehydration. Another procedure to relieve bronchial obstruction is dehydration. In recent years attention has been directed toward the relation between electrolyte balance and asthma. In practice, the measures employed are a low salt diet or a low sodium acid-ash diet, often in combination with a potassium salt of iodine or chlorine. Actually, these are measures for tissue dehydration, and perhaps in this way they open the bronchial lumen by causing a shrinking of the bronchial wall.

My own practice for years has been to place severe cases on fluids, weak tea, fruit or vegetable juices without salt; to give vigorous catharsis, using compound cathartic pills, 2 at night; magnesium sulfate, 1/2 ounce in the morning, followed three or four hours later by an enema or preferably a colonic irrigation. With enough sugar and sedation, this type of fluid intake can be maintained for three or four days. It has the additional advantage of lessening abdominal pressure on the diaphragm, which is important. Water may be freely given. This simple procedure I find very useful. It may be followed by small, frequent salt-poor feedings. Foods that may be a cause of asthma are excluded. Keeney has suggested tissue dehydration by the use of 50 per cent sucrose, 50 to 100 cc. intravenously, and it succeeds temporarily in some cases, especially when 0.2 to 0.4 cc. of epinephrine is added to the sucrose.

(*c*) A third method used with success in some cases aims to remove the mucus plugs by suction through a bronchoscope. Such a procedure should be accompanied by the simultaneous use of epinephrine 1:1,000 subcutaneously. Of course, this is not practical for frequent use.

Relief of Oxygen Deficiency.—Oxygen is of great help even when cyanosis is not marked. Asthmatic patients dislike tents and masks, as a rule. I prefer to use nasal catheters and have found them most practical. Whether to use oxygen alone or with helium is a moot question. The expense of helium is prohibitive when the open method is used and many of my patients in status asthmaticus do not tolerate the B.L.B. mask or tent. Actually, the oxygen alone by nasal catheter seems to be entirely satisfactory.

Measures for the Rest and Comfort of the Patient.—Under this heading we first have sedation. The mental anxiety and tension of these patients must be relieved by drugs. The barbiturates are useful but usually not sufficient. Paraldehyde, 1 to 3 drachms in water with syrup

instillation, but I was thinking about systemic administration.

DR. COOKE: I think it has an effect. Just as we see patients obtain relief from nasal blockage from the oral administration of one of the ephedrine compounds, so also they receive relief from injected epinephrine. I believe patients get as satisfactory results by taking ephedrine or some of its modifications by mouth as by use of the nasal spray. The danger of local vasomotor reaction is absent.

STUDENT: Does adrenalin fastness ever occur?

DR. COOKE: Whether "fastness" is a correct term or not I am not at all sure. What we generally mean, I think, when we say "adrenalin-fast" is that the patients do not get symptomatic relief, not that they do not get the other effects of adrenalin. I doubt very much whether there is such a thing as adrenalin fastness in the sense that the drug has ceased to exert any pharmacologic effect. If we took blood pressures, or if we watched for the pallor and the tremor, we would see that patients get those effects. Of course, there are many patients who do not get symptomatic relief following the injection of epinephrine, but that is rather because of the character of the bronchial lesion and the condition of the plugging of the bronchi with inspissated plugs of mucus.

In some patients, however, in whom the adrenalin does not seem to produce a satisfactory clinical response, I think aminophylline is often of very great benefit.

It seems to me a little unfortunate that we do not know more about how that drug acts in asthma. I am not aware of any studies which have thrown light upon the pharmacology of aminophylline in asthma.

DR. GOLD: Is it not likely to be due to a depression of the smooth muscle? In animal experiments, bronchospasm is readily relieved by the xanthines as a group. Or would you think that is not the explanation?

DR. COOKE: I think it is one of the possibilities, but in addition to that, it may be that in the bronchi it helps also because it dilates the blood vessels just as it does in the skin to produce the flushing. It may do the same thing in the mucous membrane and help to free and wash out the plugs of mucus by increasing the secretion somewhat, the same as potassium iodide does. Whether or not the dyspnea of asthma is really the result of bronchial constriction is still a moot question.

There is not very much evidence that spasm of the smooth muscle of the bronchi is a very important factor in the production of the asthmatic dyspnea. Witness, for example, the fact that in the pathologic studies we see some hypertrophy of smooth muscle fibers of the bronchi in asthma, but we also see greater hypertrophy in chronic bronchitis which is not characterized by dyspnea. Pathologic studies certainly indicate that in the status asthmaticus cases the major part of the obstruction is due to the actual blocking of the bronchi with the accumulations of mucus, characteristically a very tough, tenacious mucus that even at autopsy can be removed only with difficulty. It is like a rubber stopper when you try to pull it out from the medium-sized or even the larger bronchi.

DR. GOLD: Dr. Cooke, you spoke about dehydration, and you mentioned the use of sugar solutions and also the potassium salts in an endeavor to effect dehydration. We have very much better agents for dehydration than either one of those. Mercupurin can dry people up very effectively.

DR. COOKE: We have tried it in a few cases. It did not in those instances show outstanding results, but I think it would be worth further trial.

DR. TRAVELL: Would it not be more logical to try to liquefy the thick mucus plug?

DR. COOKE: Yes, it would, but we have no agent that I know of at the present time that is particularly satisfactory other than the potassium iodide, which, while useful in many cases, is certainly inefficient in most of them.

STUDENT: I should like to ask what the value of alcohol is in treating asthmatics? If there is any, would that be because of the dehydrating process?

DR. COOKE: We do not prescribe it, but patients use it. I can recall patients who have told us that they know one way of getting relief when they have a very bad time and that is to take enough alcohol to get good and tight. It is probably the sedation rather than any other effect such as dehydration which is helpful. They simply forget their troubles for the time being.

Summary

DR. WALTER MODELL: The treatment of hay fever depends on whether it is of the vasomotor or the hyperplastic type. In the former, treatment consists in avoiding the cause, in immunization, and in symptomatic medication, while in the latter type in which irreversible changes in the nasal mucosa have probably developed and infection may be established, the attempt is made to avoid irritants and to eliminate the infection, by specific (preferably autogenous) vaccines, or surgery if all else fails, and by purely symptomatic treatment.

For the treatment of asthma, the atopic and infective types are separately considered. In

used today to designate the group which will give positive cutaneous or eye reactions, the group which is "skin-sensitive," so to speak, and in which the cause can be determined by a skin test or an eye test. This is not the case in bacterial allergy.

DR. GOLD: Is that not also true of some cases of so-called bacterial infections?

DR. COOKE: In asthma of infective origin we have no test other than the symptomatic test—that is, the production of asthma by the injection of vaccine. We find positive skin tests in infective cases when we have a combination of atopic plus infective manifestations. There is, I think, a good reason for a differentiation of the two types because immunologically they are strikingly different.

DR. GOLD: In what respect?

DR. COOKE: In the one case, the atopic, we have the skin-sensitizing antibody which can be demonstrated by taking the serum of sensitive persons and passively sensitizing a normal skin. That can never be done with the bacterial cases; these give no evidence of a skin-sensitizing mechanism.

DR. GOLD: Are there any other questions?

STUDENT: How real is the danger in the use of epinephrine for an asthmatic attack in cases with hypertension?

DR. COOKE: I do not think hypertension is a serious contraindication. We have had to use it frequently for the relief of an asthmatic paroxysm in such patients. Of course, the actual increase in tension created by epinephrine is not very great, and is not very longstanding, and the relief from the dyspnea is, of course, a very real thing.

It is not uncommon in patients with a moderate degree of hypertension and severe asthma to find, after an injection of adrenalin, that with relief of asthma the pressure goes down rather than up. In other words, the quieting or the lack of respiratory effort, as well as the lack of tension, resulting from comparatively quiet breathing, are in themselves factors in the reduction of pressure following the use of adrenalin.

DR. WHEELER: How often do you find it necessary to give adrenalin intravenously in extremely severe paroxysms? Is it ever advisable? Is it ever necessary?

DR. COOKE: I think the only occasions in which we have used it intravenously are in cases of shock reactions following an overdose, let us say, of a pollen extract or horse serum. In such instances we do at times want prompt and immediate relief; but with more standard methods of preparation and with a better knowledge of allergy, our serious constitutional reactions today are minimal and I have not seen an intravenous injection given for perhaps the last five years. However, we have had to use them at times and that was, of course, for the reactions following an accidental serum administration on the ward to a serum-sensitive person.

In those very serious cases the size of the dose is not of particular importance. Severe adrenalin reactions do not occur even from a fairly large dose. One could, in an emergency like that, give 0.5 to 1 cc. of a 1:1,000 solution intravenously without producing any serious effect.

DR. GOLD: That is remarkable.

DR. COOKE: On the other hand, where one is giving it with the sucrose in the ordinary case of persistent but severe dyspnea one gets quite a prompt effect from 0.2, 0.3, or 0.4 cc., even when diluted in 50 to 100 cc. of sucrose.

DR. GOLD: You would not like to have it made a general practice to give intravenously 0.5 cc. of 1:1,000 of epinephrine?

DR. COOKE: Certainly not. It is indicated only in cases reacting acutely after a dose of some allergen such as serum when the result might be fatal.

DR. GOLD: Are there any other questions?

INTERN: What anesthetic is recommended for operation in the moderately severe chronic asthmatic?

DR. COOKE: In the asthmatics we have used avertin, about 70 mg. per kilogram, for the primary anesthesia. Dr. Grove seems convinced that these patients are apt to have respiratory difficulty during operation with avertin anesthesia, and he has been inclined to discontinue its use. In the last six months or so he has used ether alone for anesthesia. These patients take ether anesthesia very well.

DR. TRAVELL: How about the use of atropine in allergic rhinitis in hay fever?

DR. COOKE: There it is useful, and I think the doses need to be very small.

DR. WHEELER: Dr. Cooke, do any of these newer vasoconstrictors like neosynephrin have any advantage over the older ones, like ephedrine, in the treatment of allergic conditions?

DR. COOKE: No, I do not think so. Most of us use neosynephrin, especially in the nasal cases, as a 1 or 2 per cent spray. I think we have seen more trouble from neosynephrin than perhaps we did from the ephedrine itself. I cannot see that it has lessened the reactions which follow its persistent use.

DR. GOLD: Dr. Cooke, does a dose of ephedrine by injection have any effect on the symptoms in hay fever?

DR. COOKE: Yes, it will relieve an acute nasal blockage temporarily just as it relieves asthma.

DR. GOLD: Of course, it is widely used by

Case Report

INTESTINAL OBSTRUCTION, BILIARY CALCULUS, SENILITY, OPERATION, RECOVERY

HENRY J. VIER, M.D., White Plains, New York

INTESTINAL obstruction resulting from gallstones is of infrequent occurrence, but when it is encountered it is of grave consequence. A recent comprehensive review of the literature by Foss and Summers* ably presents the subject and quotes the oldest patient in the literature reviewed as being 83 years old. The type of treatment in this case is not stated, and whether or not recovery occurred is apparently not known. One of my own cases reported herein is, to the best of my knowledge and belief, the oldest patient on record who has suffered from this condition, was operated upon, and has made a prompt recovery.

Case Report

Mrs. M. McH. (Case No. 724), aged 86, entered St. Agnes Hospital at 7:00 P.M. March 13, 1942, with a chief complaint of severe, cramp-like abdominal pain, accompanied by nausea and vomiting. The onset of the pain occurred eight hours before admission.

She gave a past history of an operation for procidentia twenty years before, with good result. She had remained active and vigorous since then and possessed exceptional mental acuity. In November, 1936, she suffered for about three weeks from slight upper abdominal pain, with nausea and vomiting. No particular tenderness or rigidity was then observed, and no masses were palpable, but a few days following the onset of the attack jaundice developed and persisted for two weeks. All symptoms gradually abated with palliative treatment, but her weight dropped from 152 pounds to 112 pounds in about six weeks.

She then remained active and symptom-free until December, 1941, when she had a similar attack, this time without jaundice or noticeable weight loss. She improved gradually with rest, sedation, restricted diet, ice bag, etc. She was incapacitated at that time for four weeks.

Early on the day of admission her bowels had functioned well, but repeated enemata after she entered hospital were ineffectual. Her temperature was 97.8 F., pulse 78, respirations 26.

Physical examination revealed a very old woman in obvious pain. Eye examination showed the sclera to be clear, the pupils equal and reacting normally to light and accommodation. The patient had both upper and lower dentures. The throat was negative, and there was no enlargement of thyroid or palpable cervical nodes.

The chest was negative, with regular heart sounds, good tone, and no murmurs. Blood pressure was 148/80.

The abdomen was very slightly distended, with moderate, generalized tenderness and rigidity but no palpable masses. Digital examination of the rectum was negative. The extremities were negative.

Examination of the urine showed it to be straw-colored, cloudy, and acid. Specific gravity—quantity was insufficient; reaction for albumin was 3 plus, and for sugar it was negative. Blood examination revealed innumerable leukocytes per high power field, with clumping, no casts, 20 to 25 red blood cells per h.p.f., and large amount of amorphous urates.

The blood count was as follows: erythrocytes, 4,690,000; leukocytes, 15,600; hemoglobin, 83 per cent (Newcomer); polymorphoneutrophils meta II, 9 per cent, segmented, 85 per cent; lymphocytes, 5 per cent; mononuclears, 1 per cent. The blood examination showed the following: hematocrit, 48 per cent; plasma specific gravity, 1.0268; plasma proteins, 6.76 per cent; blood chlorides, 290 mg. per 100 cc.

A flat plate of the abdomen was reported as follows: "Roentgenogram made of the abdomen in the anteroposterior direction shows no abnormal collection of gas suggestive of intestinal obstruction. The outline of the intestines is shown distinctly, and they are normal in size, shape, and position. The psoas margins are sharply outlined. There is a moderate degree of osteoarthritis involving the spine and sacroiliac articulation."

Wangensteen drainage was instituted. Morphine sulfate, 1/6 grain every six to eight hours, as required to control pain, was administered. She received intravenously 500 cc. of 5 per cent sodium chloride, followed by 500 cc. of plasma, 1,000 cc. of 5 per cent glucose in distilled water, and finally 1,000 cc. of Hartmann's solution. All were given slowly.

The pain persisted throughout the night. On the [illegible], the patient presented [illegible] distension. A metallic [illegible] stethoscope, and the greatest tenderness was just to the left of the umbilicus, where a few slightly distended coils of small bowel were palpable. Twenty-five ounces of apparently duodenal contents were observed from the Wangensteen drainage. Another blood examination showed the following: hematocrit, 52 per cent; specific gravity of plasma, 1.0267; plasma proteins, 6.73 per cent; and plasma chlorides, 412.5 mg. per 100 cc.

Operative interference was decided upon, and no attempt was made to use the Miller-Abbott tube. The patient was taken to the operating room at 11:40 A.M., March 14, about twenty-four hours following the onset of her pain. The following is the record of her operation:

"Small amount of clear fluid noted in the peritoneal cavity. Small bowel slightly distended to point from approximately 2 to 3 feet proximal to the ileocecal valve. Obstruction due to exceptionally large gallstone, impacted in the lumen. No further effort was made to explore the abdominal cavity.

* Foss, Harold L., and Summers, J Dent: Ann. Surg. 115: 721-735 (May) 1942.

general their treatment corresponds to that of the vasomotor and hyperplastic types of hay fever, the atopic type of asthma to the former, the infective asthma to the latter. In the former the cause is avoided and immunization is to be tried; in the latter the primary move is against the infection. These outlines follow the generally accepted and well-known patterns of treatment and the details need not be repeated here. What is more in need of emphasis, perhaps, is the treatment of the urgent symptoms and occasional emergencies which do arise and which are not frequently treated by those in general practice. These are the situations which give difficulty when often some simple procedure will bring prompt and dramatic relief.

Bronchial obstruction presents one of these urgent situations. For this condition 3/8 grain of ephedrine by mouth with or without a sedative dose of some barbiturate, or vaporization with 1:100 (not 1:1,000) epinephrine, or a subcutaneous or even an intravenous injection of epinephrine may give relief. For less acute symptoms, 2 mg. of "slowly absorbed" epinephrine (in oil or gelatin) has advantages. Aminophylline, 0.5 Gm. intramuscularly, is also of occasional help.

Oxygen is of use to overcome the oxygen deficiency but it should be remembered that asthmatics usually tolerate nasal catheters better than masks. Dehydration sometimes helps in bronchial obstruction. In practice a low salt diet or a low sodium-ash diet together with an iodide or a chloride of potassium (0.3 to 0.6 Gm. potassium iodide or potassium chloride three times a day) is useful. One successful plan places the patient on such a regimen, and cathartics are administered morning and evening. With sufficient sedation some patients tolerate this treatment for a few days and obtain relief. Bronchial plugs may be directly removed by suction.

For severe reactions following the administration of allergens it may be necessary to administer epinephrine subcutaneously, or in very urgent cases, a small dose intravenously.

ANOTHER RAGWEED POLLEN SURVEY

For the benefit of hay fever victims in New York State who seek havens of relief during the summer and fall, the New York State Department of Health will conduct another survey this year in the Adirondack mountain section to obtain additional information on the concentration of ragweed pollen in the atmosphere.

Preliminary plans call for the installation of pollen count stations at Old Forge, Indian Lake, Speculator, and Loon Lake. All these places are on the rim of the area known to be relatively free from ragweed and its pollen. The purpose of placing the stations in these communities will be to determine whether or not the "free" area has enlarged as the result of ragweed eradication programs which have been in progress in this vicinity for several years.

Similar pollen count stations have been operated by the Department since 1937 with the exception of last year. With the assistance of volunteer attendants, it is expected that the stations will be opened about the middle of August and continued until the first fall frosts. Oil-coated glass slides will be exposed for periods of twenty-four hours each under protective roofs which will permit free movement of air across the oiled surfaces. These slides, which will provide a permanent record of intensity and concentration of ragweed pollen in the air during the season, will be examined under the microscope and the findings recorded for each day of exposure. The results will be available late in the fall after the final counts have been completed.

The Division of Public Health Education will send pamphlets on hay fever and ragweed, together with maps of the "pollen-free" area, to anyone in the state upon request.

DR. S. S. GOLDWATER MEMORIAL FUND

Under the will of the late Dr. S. S. Goldwater, former commissioner of hospitals of the city of New York, Mount Sinai Hospital will receive a sum of money which with supplementary gifts from Mrs. Goldwater will be used to establish a fellowship in hospital administration to be known as the Dr. S. S. Goldwater Memorial Fund. Students and workers in hospital administration who qualify will receive $1,000 annually.—*Medical Record*

FELLOWSHIPS IN HEALTH EDUCATION

The United States Public Health Service has received a grant from the W. K. Kellogg Foundation for the establishment of 20 fellowships leading to a master's degree in public health with a major in health education. The grant will help to meet the need for qualified educators to carry on essential health education both during and after the emergency. The training, which began on March 20, is being given at the University of North Carolina.

It is apparent that this patient, during the time of the recent acute cholecystitis, established a fistula between the gallbladder and the duodenum, through which the large stone causing the obstruction passed."

Procedure.—Following the usual preparation and under regional anesthesia (novocain 1/2 of 1 per cent) a mid-left rectus incision was made, hemostasis was accomplished, and the peritoneal cavity was opened.

Saline tapes were inserted, and at this point G.O.E. anesthesia was begun. The exploring hand readily found the point of obstruction, which was delivered into the wound, and after both limbs of the small gut were "milked back" from the point of obstruction, a soft, rubber-covered clamp was applied. The bowel was grasped with Babcock clamps, and an incision was made in the antimesenteric portion of the bowel in its long axis, with the gallstone, about 3 1/2 cm. in diameter, being lifted out with forceps. The bowel was then sutured in the opposite direction in order not to decrease the diameter of the lumen. First a layer of fine, interrupted chromic catgut was used, and this, in turn, was covered with two additional layers of interrupted sutures of the same material. Five Gm. of sulfathiazole were then placed in the operative area, and the wound was closed with through-and-through steel wire alloy sutures. Clips were put in the skin, and dressings were applied. During the operation, the patient received 500 cc. of plasma. Her immediate postoperative condition showed practically no shock.

The Wangensteen suction was not interrupted during the course of the operation. Forty-eight hours postoperatively the patient developed a pneumonic process at the base of the right lung, which promptly cleared up with sulfathiazole therapy and the use of an oxygen tent.

She experienced very little discomfort and vomited a small quantity of bile-stained fluid on two occasions. She expelled flatus freely on the first day after operation, and the following day her bowels functioned spontaneously and freely. On the fourth postoperative day she again vomited, this time evidently as the result of the sulfathiazole, for when this was discontinued, the vomiting ceased.

Fluids and plasma were given as their need was indicated by repeated blood studies. Ascorbic acid, 100 mg., was administered hypodermically once daily.

The patient celebrated her eighty-sixth birthday on her fourth postoperative day.

Her wound healed per primam intentionem, and she was discharged from the hospital on the seventeenth day after operation. She called at my office on May 23, 1942, and reported that her appetite was good, and her bowels functioned daily. She had lost no weight, and she had suffered no indigestion or pain.

PHYSICIAN'S HANDBOOK ON RHEUMATIC FEVER

Rheumatic Fever in Children—Its Recognition and Management, a 32-page clinical handbook written for the practicing physician, has just been released by the Metropolitan Life Insurance Company.

It assembles under one cover the modern concepts of the disease—its nature, diagnosis, and prognosis and the individual and community problems involved in the care of the patient. A group of distinguished clinicians and the following organizations assisted in its preparation: the American Heart Association, the American Academy of Pediatrics, the Children's Bureau of the United States Department of Labor, and the United States Public Health Service. Other educational material has been developed by the Company in connection with its national program to reach the general public and the medical profession with information on this disease.

Single copies of the handbook are being made available to physicians, without charge, chiefly through the 16,000 field representatives of the Metropolitan Life Insurance Company. Physicians who wish a copy, and who have not obtained one by June 1, should write to Dr. George M. Wheatley, Assistant Medical Director, Metropolitan Life Insurance Company, 1 Madison Avenue, New York, New York.

U.S. PUBLIC HEALTH SERVICE FEATURED IN FILM

Dr. Carl E. Rice, currently in charge of the Community Medical and Dental Section of the U.S. Public Health Service at Bethesda, Marlyand, is featured in RKO's "Medicine on Guard," which tells the story of the typical wartime community faced by urgent health problems arising from the shortage of doctors.

Dr. Rice works in close cooperation with the Procurement and Assignment Service of the War Manpower Commission and when appealed to by the harassed local physician he arranges the relocation of a doctor from a less critical area. This latest "This Is America" two-reel feature depicts the rising incidence of tuberculosis in a typical industrial community, and again it is the U.S. Public Health Service that comes to the rescue. Under the direction of Dr. Herman E. Hilleboe, this menace is being checked through the use of the mobile photofluorographic units which are set up in the factories themselves and take mass chest plates of the workers with a minimum of time loss and expense. The elaborate laboratories of the Bureau of Industrial Hygiene under the direction of Dr. James G. Townsend are shown determining the causes of occupational disabilities and thus keeping the industrial health of America at its usual high level. These aspects of the U.S. Public Health Service's home-front battle against sickness and disease are illuminatingly and entertainingly filmed in "Medicine On Guard."

House of Delegates

Minutes of the Annual Meeting

[*Continued from page 1169, June 15 issue*]

Morning Session

May 4, 1943

The session convened at 9:00 A.M.

SPEAKER BAUER: The House will be in order. Has anyone any further resolutions to introduce?

....There was no response.....

SPEAKER BAUER: If there are no resolutions, we will proceed to the reports of the Reference Committees.

Section 77

Report of the Reference Committee on Report of the Council—Part X: Public Relations and Economics

DR. W. W. STREET, *Onondaga:* The committee's report on its yearly activity is largely informative. No recommendations are included.

We note with sorrow the passing of the former chairman, Dr. Augustus J. Hambrook. His loyalty and qualifications are well known to this House of Delegates and to the medical profession of New York State. We sincerely regret his loss, and we cherish his memory.

The work of the committee has been very ably carried on under the leadership of Dr. Herbert H. Bauckus, who, as a member of the committee, was familiar with the problems at hand. As stated in this report, the most important function of organized medicine has been its part in promoting the winning of the war. This committee has cooperated to the full extent in this effort.

Nursing Shortages. This committee met with the New York State Nursing Council For War Service to discuss and obtain a free exchange of opinion to enable the country to obtain the maximum amount of service from the much needed but limited nursing personnel. It is planned that further conferences on this matter will be held. Your reference committee is in hearty accord with this effort and recommends its continuance.

Workmen's Compensation Problems. During the year, several conferences were held with Dr. David J. Kaliski, director of the Workmen's Compensation Bureau, concerning various phases of compensation problems. It was especially emphasized that county societies should adhere to the minimum fee schedules as a standard for evaluation of medical services, especially with groups. Other questions, such as raising some of the items in the Workmen's Compensation Fee Schedule now in effect and the present application of the principle of free choice of physicians by the employee, were also discussed. Undoubtedly these questions will be reported more in detail in the report of the Workmen's Compensation Committee. Your reference committee recommends the continuance of close cooperation between these committees in the administration of this law. The physician, in active practice, must also do his part to make the law work successfully and smoothly.

Intern Insurance. Your reference committee notes with satisfaction the obtaining of the ruling from our Counsel that interns and resident physicians in hospitals come under the Workmen's Compensation Law when affected by accident or any compensable disease.

Industrial Examinations. Your reference committee heartily commends the committee for reemphasizing its code of ethics to the effect that rejection or demotion of any person shall be based solely upon accepted medical and scientific criteria in industrial physical examinations.

Farm Worker Problem. Your reference committee heartily approves the efforts of this committee in solving the problems of medical care of indigent migratory farm workers.

Coroner System. Your reference committee is in sympathy with the committee's effort to improve the present coroner system to the end that postmortem examinations should be done by properly trained pathologists. It is hoped that continued effort will be made to bring this about.

The work of this committee brings it in touch with many of our other committees, as it bridges the gap between organized medicine, on the one hand, and the lay people of the State on the other. It is hoped that the committee will continue to function with the same high quality of service as in the past.

I move the adoption of the report, which is signed by William W. Street, chairman, David Corcoran, Edwin A. Griffin, William Klein, and Henry S. Martin.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

SPEAKER BAUER: Thank you, Dr. Street!

I should like to say this about Dr. Street: The chairman of the committee was unable to be here, and the night before this House met, Sunday night, I called Dr. Street and asked him if he would take over the chairmanship, which he very kindly consented to do. I appreciate very much his being willing to step into the breach on such short notice.

Section 78. (*See 23*)

Report of Reference Committee on New Business B—Full Citizenship as Requirement for License to Practice

DR. ALBERT G. SWIFT, *Onondaga:* Regarding the resolution on full citizenship for licensure to practice medicine, your reference committee has given careful consideration and study to the resolution presented by Dr. Noehren, of the County of Erie, reading:

"WHEREAS, full citizenship has not been required for the securing of a license to practice medicine in New York State; and

"WHEREAS, most foreign countries will not allow United States physicians who are not citizens to secure a license to practice; and

"WHEREAS, many foreign physicians who have not been in this country long enough to secure citizenship or become acquainted with the ethics and customs of American medicine; and

rectify the mistakes of the past. I plead for time to solve this problem.

DR. JOSEPH C. O'GORMAN, *Erie:* It seems to me the question is: What is the opportune time? I am sure we can have faith in our Council to determine that. They are the ones in the best position to judge, and that is the purpose of my resolution. I think the amendment—as to who, and when, and where the opportune time—should not be left to this immediate body, but rather to the men whom we select to represent us in the interim. I cannot see why we should immediately determine that question here, and I speak in favor of the resolution.

Does the committee feel that it is the Council that is going to determine the opportune time? Is that part of the report?

DR. SWIFT: Yes.

DR. SIMPSON: I just want to add a thought on this matter. The situation is not as simple as it appears on the surface. When you consider and speak of foreign physicians you have to include Canadians also. Until we definitely get the situation of Canada straightened out, and with that the implications that come from the national government's refusal to allow the status in New York to be disturbed at the present time, we cannot hope to succeed.

Although the leaders of the Legislature feel that something should be done and I think the Board of Regents feels very strongly that citizenship should be required, we were told very definitely that this is not the opportune time to do it.

SPEAKER BAUER: Dr. Bedell, you wanted the floor again?

DR. BEDELL: Yes, sir.

Gentlemen of the House, this is the committee of the whole, which is always greater than a committee of this body, a part. There are more minds at work on this floor on this situation than could possibly gather in a committee. I think if we took the individual and asked him what he thought of his individual community he would say now is the time.

It is all very good for us to be sentimental on the other side, but we are very remiss when we allow these men to come in and become established and thus take the place of our boys that are at the front, and it is time that we began to think of those men. They are the ones that are saving this country, and we are not doing our share to protect their practice for them until they return if we do not take this action now.

It matters little to me personally, but all we do year after year is to say, "No, no, not now." The Board of Regents is also looking for strength to uphold them in their decision. Are we in any way helping them when we fail to take action?

I really think, gentlemen, that the time has come when you should think more of the boys that are away than of those who have come here.

SPEAKER BAUER: Is there any further discussion? If not, the question is on the amendment. The original motion of the committee was that the resolution should be changed to the effect that while full citizenship should be required, the time at which it should be demanded would be left to some opportune time, not definitely stated. The amendment is that the House should recommend that full citizenship be required now. The question is on that amendment. All those in favor of the amendment will say "Aye"; those opposed, "No." The motion appears to be lost, but I think we will take another vote to get the division. Those in favor of the amendment will please rise; those opposed to the amendment will please rise. The motion is carried 58 to 40.

We now have the amended motion before you for consideration. The amended motion is that the House recommend that full citizenship be required now for licensure. Is there any further discussion on the amended motion?

....There was a call for the question, and the motion as amended was put to a vote and was carried.....

Section 79. (*See 33*)

Report of Reference Committee on New Business B—Suggested Amendment to Federal Compensation Act Covering Longshoremen and Harbor Workers

DR. SWIFT: The next report is on the following resolution presented by Dr. Peter Murray, concerning an Amendment to the Federal Compensation Act, reading:

"WHEREAS, employees working as longshoremen and harbor workers are covered against injury or death resulting from accidents while at work by the Federal Compensation Act (Public-No. 803–69 Congress) known as Longshoremen's and Harbor Workers' Compensation Act; and

"WHEREAS, the employer of such workmen is obligated to furnish such medical, surgical, and other attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus for such period as the nature of the injury or the process of recovery may require; and

"WHEREAS, physicians in the neighborhood of docks and harbors where such injury may occur have given such injured employees emergency treatment and have had the patient taken away from them by the employer or his agent and sent to the physician preferred by, or under contract with, the employer; and

"WHEREAS, such physicians who have treated such injured employees have difficulty in collecting fees for services rendered, even for emergency treatment; and

"WHEREAS, the employee, by such procedure, is deprived of free choice of a physician as provided for by the New York State Workmen's Compensation Law and advocated by the ethics of the American Medical Association; therefore, be it

"*Resolved*, that it is the consensus of opinion of the New York County Medical Society that the Federal Compensation Act known as Longshoremen's and Harbor Workers' Compensation Act be amended to allow injured employees to be treated by a physician of their own choice with whom they may stay until the completion of treatment."

We recommend that this resolution, presented by Dr. Murray, for the New York County Medical Society, be adopted. I so move.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

Section 80. (*See 46*)

Report of Reference Committee on New Business B—Planned Parenthood

DR. SWIFT: Concerning the resolution presented by Dr. Trembley, of Franklin County, reading:

"WHEREAS, the American Medical Association has recommended in its resolution of June 8, 1937, that the legality of the use of contraceptives be

"WHEREAS, many of these foreign physicians are not familiar with the health problems and the laws of this State; and

"WHEREAS, there is an undue concentration of refugee physicians in New York State due to the fact that most states insist upon citizenship as a requirement for licensure; therefore be it

"*Resolved*, that the delegates representing the Medical Society of the County of Erie be instructed to petition the House of Delegates of the Medical Society of the State of New York to pass a resolution favoring full citizenship as a requisite for securing a license; and be it further

"*Resolved*, that the Legislative Committee of the Medical Society of the State of New York take steps to have introduced legislation to modify the requirements for licensure so that full citizenship will be a prerequisite."

We note that this problem has been studied by a special committee and that they have made the following recommendation in their report on the status of foreign physicians. They recommend as follows:

"Change the Education Law, Section 1256, Chapter 1, to read: 'Is more than 21 and is a citizen of the United States.'

"Delete 'or has declared his intentions of becoming a citizen' or change the requirements by rule of the Board of Regents."

They further recommend that such a move shall be made at an opportune time.

Your committee recommends that this recommendation on the status of foreign physicians be endorsed.

SPEAKER BAUER: I take it that the committee, then, recommends that on the question of requiring full citizenship for licensure action should not be taken until an opportune time presents itself. Is that correct?

DR. SWIFT: Yes. I move the adoption of this report.

....The motion was seconded.....

DR. ARTHUR J. BEDELL, *Past-President:* Question of information: Who is to interpret this opportune time?

SPEAKER BAUER: Does the committee wish to answer that?

DR. SWIFT: No, I think the House of Delegates should interpret the opportune time.

DR. BEDELL: I would then propose an amendment: Now is the opportune time.

SPEAKER BAUER: Dr. Bedell proposes an amendment that the House recommend that citizenship be required now.

DR. THOMAS B. WOOD, *Kings:* I second the amendment.

SPEAKER BAUER: The amendment has been made and seconded that now is the opportune time for requiring full citizenship. The discussion is on the amendment.

DR. THOMAS M. D'ANGELO, *Queens:* I was on the committee that proposed this recommendation. This matter was given very careful study, and we felt that in view of the situation this was not the opportune time.

I think we all feel that sooner or later full citizenship should be required of all men who practice medicine in the State of New York, but at the present time, when we are engaged in this war, and when in the press and everywhere else there are statements to the effect that there is a supposed shortage of physicians, and when the question especially of race discrimination would be brought forth, your committee feels—and strongly feels—that this is not the opportune time.

SPEAKER BAUER: Is there any further discussion?

DR. BEDELL: May I have the floor?

SPEAKER BAUER: If no one else wants it.

DR. LEO F. SIMPSON, *Monroe:* This matter was taken up by the Legislative Committee this year at the request of the Council with the leaders in the Legislature, and we were flatly turned down on it at this time.

DR. BENJAMIN M. BERNSTEIN, *Kings:* May I have your indulgence for just a few moments? We have two problems involved in this resolution, which must be separated if we are to think clearly and intelligently and unemotionally, if you please.

We have the problem, as I understand it, of the Canadian physician who comes to the northern counties of New York State—comes voluntarily in order to find a better field in which to practice medicine and to earn his money. That problem should be solved undoubtedly, in my humble opinion, by requiring full citizenship.

We have another problem which in its eventuality should also require full citizenship. I take no back seat to any man who is proud of his citizenship and the rights of that citizenship. I have always believed that a man to practice a profession anywhere in this country should first be a citizen of the United States; but we have a problem arising at the present time as an outgrowth of this war and the world catastrophe, which is a thing quite apart. We have men and women who have been dislocated for no reason of their own and because of no choice of their own—men and women who have been drawn out of their beds in the middle of the night and told to go to concentration camps and ordered away from the place where they were born and where their families had lived and resided and prospered for generations. These people have been dislocated and have been brought to these shores as a haven of refuge. While I do not say that these people should be permitted to practice medicine when they arrive here simply because they are refugees, nevertheless we must solve this problem in another way.

I am perfectly willing that citizenship be a requisite for practice in New York State if we take care of the refugee physicians in some other way.

At the National Conference of Post-War Planning in the Waldorf-Astoria Hotel some weeks ago, Frederick H. Keppel, formerly dean of Columbia College and now employed by the United States Government, gave a solution which we must adopt if we are to accomplish two things: first, permit the refugee physician to practice temporarily anywhere in the United States, with a special dispensation from the United States Government in order to prevent relocation of other physicians and provide necessary medical care in those areas where a shortage exists at the present time. In the meantime these people would have the opportunity to take out citizenship if they please, or, God willing, when this war is over they may go back where they came from if that is their desire.

It appears to me that we should step lightly on this problem at the present time for humanitarian reasons primarily. We in New York State are peculiarly situated in that we are the only state in the country that at the present time does not require citizenship.

Well, we have been remiss. We have been remiss a long time. However, this is hardly the time to

SECRETARY IRVING: This is very interesting to me, gentlemen, because I think that there is something of value in it.

First, to answer what has just been said about committees changing with the first of the year in many county societies, it seems to me that the county societies can well imitate or follow the scheme set up in 1937 when we changed our State Society's method so that committees are continuing committees, even though they have to be reappointed with the change of administration. That is one of the reasons why they do better work, so I think that that argument against it goes out of the window.

I do not see why we cannot have the legislative committee chairmen and the secretaries come together at the same time in a conference of secretaries and then shift over to the legislative people, in that way making rather a fuller and a better conference of representatives of county societies in the fall

DR. ARANOW: May I ask for the floor for Dr. Lawrence on this? I should like to know his opinion

SPEAKER BAUER: The Chair will be glad to give the floor to Dr. Lawrence if there is no objection

DR. JOSEPH LAWRENCE: Certainly I see no objection to having this conference in December I think the objection was a valid one with regard to whether the conference will be a conference of chairmen who will be carrying on in the coming year About half of our county societies have their annual meetings in December, and the new president does not usually get his new committees announced until well after the first of the year We have a great deal of difficulty in getting the names of the chairmen of the county society committees in order to have them on the list of the first bulletin, which comes out about the tenth of January

Whether we can deliberate upon the legislation that is to be considered in the coming year—that, of course, would be purely a matter of guess I think it would be good for us to know the procedures that we might have to follow concerning certain measures Take, for instance, the one you have just adopted here regarding full citizenship We will certainly need to have some consideration on how we are going to proceed to advance a measure of that kind, and that could be considered at a conference, but, aside from that, we are in no position at all to act upon any legislation until we see the printed bill. That is why we have our conferences usually in the latter part of January or the first part of February, because then the bills that are coming up are usually before the Legislature, and you can see them in printed form and at the same time the Legislature has usually taken no action by then

So this measure is good in the sense, I believe, as Dr. Irving has said, that conferences between the representatives of the county societies have a very definite value in increasing the morale of the society in any measure that we may want to undertake

SPEAKER BAUER. Is there any further discussion?

DR. HENRY W. MILLER, *Putnam* I would like to hear the opinion of the Chairman of the Legislative Committee on this matter

DR JOHN L BAUER, *Kings* We get together, and we always have some good from that type of meeting—there is no question about it, but there is always difficulty in finding out early the legislative committee personnel of the various county societies There are, of course, some carry-overs, and that is very helpful, but there are always some legislative committees that are about to run out, and you know it happens with the administration of a county society, as it does with any other, that along in the fall there is an inclination to let things slide for the new administration. This being a war year, with travel difficult, and the men exceedingly busy, I doubt whether it would have the value and the practicality that some of you think it would have.

The point has also been made that we do not know definitely what form of legislation or just what legislation will come up, so I am rather in a fifty-fifty position on this question. If you want the added expense and want to take a chance on it and feel that it is a good thing for a war year, I will vote with you on it.

SPEAKER BAUER: Is there any further discussion?

DR LAURANCE D. REDWAY, *Westchester* Westchester's reason for introducing this resolution, as I understand it, was that it would be permissive and not mandatory. Remember that the House of Delegates meets only once a year, that the Legislature is usually out by the end of March, that there is a flood of legislation which needs very careful watching, and that it is necessary in a great many instances to follow along plans which are in the making for the legislation of the next year. This, as I say, was designed to permit the Society, if it is considered advisable, to call that extra session in the fall with, perhaps, the idea that it would facilitate the appointments of these new chairmen much more quickly than has been done in the past and, therefore, aid the Executive Officer and provide a means which could be used if necessary to condense the thoughts of the Society on the forthcoming legislation

DR ARANOW: May I say it is not necessary to have any action of the House of Delegates to permit such a meeting to be held This is permissive, but the chairman of the Legislative Committee now, if he feels it necessary, can call a meeting of the county committee legislative chairmen at any time, if he has the money to do it with

SPEAKER BAUER: Is there any further discussion?

DR SWIFT: Perhaps the resolution should be read again.

> "*Resolved*, that this House of Delegates advise the Council that it favors the holding of such an additional legislative conference with the chairmen of county society legislative committees shortly before the opening of the regular session of the State Legislature, for the purposes enumerated above, and to the end that the coordinated legislative activities of the county and State societies may be more purposeful and effective than they can be under present procedures."

It is not mandatory.

SPEAKER BAUER: Is there any further discussion? If not, the question is on the adoption of the resolution, which states that the House favors the holding of an additional legislative conference prior to the opening of the Legislature. All those in favor of the motion will say "Aye", those opposed, "No" The Chair is in doubt All those in favor please stand, now those opposed please stand The motion is carried by a vote of 55 to 36

Thank you, Dr Swift!

made clear to physicians; that the Association undertake investigation of contraceptive devices and methods; that medical students be instructed in the problems of human fertility; and that the dissemination of contraceptive advice be under medical control; and

"WHEREAS, the law of New York State, according to Justice Crane's opinion, 222 N. Y. 192 (1918), supports the physician 'who in good faith gives....(contraceptive) advice to a married person to cure or prevent disease....'; and

"WHEREAS, the public looks to the medical profession for leadership in medical matters involving the health of the people of the State; therefore be it

"Resolved, that the Medical Society of the State of New York approves the giving of information relating to pregnancy spacing and fertility, by physicians, to married women when in the opinion of the physician such advice is indicated for the maintenance of health or the prevention and cure of disease."

Your committee is of the opinion that the resolution presented by Dr. Trembley, of Franklin County, merely restates the privilege which physicians already legally possess and, therefore, do not recommend it.

SPEAKER BAUER: Do you recommend disapproval of the resolution or that no action be taken?

DR. SWIFT: Disapproval of the resolution.

....The motion was seconded.....

SPEAKER BAUER: The committee recommends disapproval of the recommendation.

DR. ARTHUR J. BEDELL, *Past-President:* I think that is unfortunate. That would lead one who read that hastily to suppose that we are against the law which we have already worked under. I believe it should be differently worded, and that no action is the proper thing.

DR. LEO F. SCHIFF, *Clinton:* I move a substitute for the committee's recommendation—namely, that, since it states something that is already in fact existing, no action be taken.

....The motion was seconded.....

SPEAKER BAUER: The substitute motion has been made and seconded that instead of the committee's recommendation that the resolution be rejected, the House state that since this is a matter which is already in vogue we take no action on it. Is there any discussion on permitting the substitute motion?

....The question was called for, and the motion was put to vote and was carried.....

SPEAKER BAUER: Now you have the substitute motion before you for consideration; in other words, that no action be taken on this resolution. Is there any further discussion?

....The question was called for, and the motion was put to a vote and was carried.....

SPEAKER BAUER: Very well, that resolution has no action taken on it.

Continue, Dr. Swift.

Section 81. (*See 29*)

Report of Reference Committee on New Business B—County Legislative Committees, Additional Meeting in Fall

DR. SWIFT: The following resolution was considered on "Extra Legislative Meeting," presented by Dr. Archibald, of Westchester County:

"WHEREAS, the Medical Society of the County of Westchester believes that the legislative work of the Medical Society of the State of New York and the various county societies would be greatly facilitated by a conference of county society legislative committee chairmen with the State Society Legislative Committee to be held in the late fall each year, in advance of the Legislative Session, in addition to the legislative conference regularly held midway during the Legislative Session; and

"WHEREAS, such a preparatory conference would enable agreements to be reached for the support of legislation mandated by the House of Delegates; would enable county societies having legislative problems to bring them in advance of the meeting of the Legislature to the attention of the other counties and of the State Committee; would enable the State Committee to inform county committees of the prospects of the forthcoming Legislative Session, and, in general, would prepare the county committees for more effective cooperation with the State Committee in its work; therefore, be it

"Resolved, that this House of Delegates advise the Council that it favors the holding of such an additional legislative conference with the chairmen of county society legislative committees shortly before the opening of the regular session of the State Legislature, for the purposes enumerated above, and to the end that the coordinated legislative activities of the county and State societies may be more purposeful and effective than they can be under present procedures."

We recommend the adoption of this resolution, and I so move.

....The motion was seconded.....

SPEAKER BAUER: It has been moved and seconded that the resolution, which in substance calls for an additional meeting of the chairmen of the county legislative committees prior to the opening of the Legislature, be adopted. Is there any discussion?

DR. JOSEPH A. GEIS, *Essex:* Mr. Speaker and Delegates, while it seems to me that this is an excellent proposition, in the past we have had our legislative conference generally in February when the Legislature was about half over; but there is one thing that makes me wonder whether it is practical or not. If you call it before the Legislature is in session, which is just before the first of the year, you may have an outgoing president in your county society with a new one coming in the first of the year, with entirely new committees appointed. The new committee on legislation might have a different idea altogether from that of the old one. I am wondering just how practical this would be in its working out.

DR. HARRY ARANOW, *Bronx:* Mr. Chairman and Delegates, I have had the experience of being on the Legislative Committee for a period of ten years. Whatever the House wants to be done now will be transferred to Dr. Lawrence, and he will have all summer to work on it. He does not know in the beginning of the session what kinds of laws are going to be produced or introduced. There are one, or two, or three things that the House is going to instruct him to do, and that will be done. I cannot see any sense in this at all. I have been to a great many meetings of these delegates from the different county societies, or rather the county society chairmen of legislation, and I cannot see anything that is accomplished by them. There is no harm in the thing, but it will be just a waste of time and a waste of money.

the option of the Surgeon General, it is very unwise to make any distinction in relation to the collection of or the remission of dues of women members of this Society as against men members who enter the armed forces. There should be the same rule for both because, as a matter of fact, today women will be commissioned in the Medical Corps of the Army of the United States exactly as the men are, so there should be no distinction between the two.

SPEAKER BAUER: I think, perhaps, we are getting a little bit off the subject. The question is that dues should be remitted for women physicians if they are serving as physicians.

DR. ROONEY: Mr. Speaker, I think we can clarify that by amending the verbiage of that resolution to state that all members of the Medical Society of the State of New York who are commissioned in the armed forces of the United States or in the Public Health Service may, upon resolution of the Council, have their dues remitted for the period of their service.

ASSISTANT SECRETARY PODVIN: I second that amendment.

SPEAKER BAUER: Would you not want to include in that, "commissioned in the armed forces or the auxiliaries," since there seems to be some question as to whether the auxiliaries are a part of the armed forces?

DR. ROONEY: The auxiliary has not been taken over by the Army. The bill for that is still pending in Congress, but it may very well be done. I don't feel that they will be commissioned in the auxiliaries; they will be commissioned in the Medical Corps of the Army of the United States. There will be no assignment of medical officers to the auxiliary as such. The substitute covers the point. It makes provision for them when they are commissioned in the armed forces of the United States or in the Public Health Service, the same as any male officer.

SECRETARY IRVING: Gentlemen, this whole matter of the auxiliaries came up in regard to one woman physician who was serving as a full-time physician in the WAACS. She was a contract surgeon, but full-time, and certainly that woman physician, in my personal opinion, deserves to have her assessments in the State Society remitted.

DR. ROONEY: Would she not now have that status? These contract surgeons, as I understand it, in the Auxiliary will be commissioned just as soon as the Surgeon General gets around to it, which will probably be in two or three weeks. We will have a new Surgeon General then, and a number of matters are being put off until Kirk takes that office. It seems to me that, whether they are contract surgeons or whether they are commissioned, if they are in the armed forces of the United States they should have their State assessment remitted.

ASSISTANT SECRETARY PODVIN: I should like to second Dr. Rooney's amendment because I think it would clarify matters a great deal. We have in our county a large veterans' hospital, with a large staff of men who are serving in the Public Health Service. These men are civil service men, but they are in the Public Health Service. They are not commissioned by any means, and we have not remitted their dues on that account. As a result there has been considerable controversy, and I should like to see the matter settled, as I think it would be by Dr. Rooney's motion.

DR. LEO F. SCHIFF, *Clinton:* May I hear Dr. Rooney's amendment?

(Dr. Rooney's amendment was read by the reporter as follows: "All members of the Medical Society of the State of New York who are commissioned in the armed forces of the United States or in the Public Health Service may, upon resolution of the Council, have their dues remitted for the period of their service.")

DR. SCHIFF: Very briefly, Dr. Rooney and I had arrived at the same conclusion, and he was a little quicker or more in favor with the Speaker than I was. (Laughter)

I simply wanted to bring out this point: All members of the Medical Society of the State of New York are members on an equal footing, be they men or be they women, and I should feel that the purpose of any resolution that we pass would be to cover all of our members equally without any distinction and to cover all who are serving our country whether in the Army, the Navy, or any other force for the duration of the war.

I certainly am in favor of the amendment and hope that it will be passed unanimously.

SPEAKER BAUER: Is there any further discussion of the amendment?

....The question was called for, and the amendment was put to a vote and was carried.....

SPEAKER BAUER: Now you have before you the amended motion for consideration. Is there any discussion on that?

....The question was called for, and the motion, as amended, was put to a vote and was unanimously carried.....

DR. MONTEITH: Let me say that your committee had no intention at all of discriminating against women physicians. We thought they were being treated the same way as the men in our report, and that is why we made the recommendation.

SPEAKER BAUER: Could we have a reading of the proposition to see whether that is fully covered?

DR. MONTEITH: "Your committee suggested that any remission of dues allowed to women physicians be continued only if their status in the various auxiliary reserves is as physicians."

SPEAKER BAUER: This suggestion was eliminated and the amendment stated that they must be commissioned in the armed forces or in the United States Public Health Service, and that has already been passed.

Have you anything further to report, Dr. Monteith?

DR. MONTEITH: Yes. Your committee desires to offer to the House of Delegates the Council's memorials of deceased officers as follows:

Dr. Terry Monroe Townsend

Dr. Terry Monroe Townsend, of New York City, served organized medicine over many years, until his death on May 16, 1942, in his sixty-sixth year.

He was an original founder of the American Urological Association, President of the New York Urological Society (Branch of the American Urological Association), 1911 to 1912. He was President of the Medical Society of the County of New York in 1933, President of the First District Branch of the Medical Society of the State of New York in 1936, and President of the Medical Society of the State of New York, 1939–1940. At the time of his death he was serving on the Committee on Grievances of the New York State Department of Education.

Dr. Townsend was a Fellow of the American College of Surgeons, and a Diplomate in Urology. He had practiced his specialty since coming to New York in 1899. He was active on the staffs of the New York City Hospital, Morrisania Hos-

Section 82. (See 13)

Report of Reference Committee on the Report of the Council—Part XII: Miscellaneous

DR. STEPHEN R. MONTEITH, *Rockland:* Your Reference Committee on Report of the Council Part XII begs to report as follows:

On the published portion of the report, we approve of Council nominations and subsequent appointments of the members as noted: Dr. Walter P. Anderton, of New York, to the Council on Grievances of the State Department of Education; Dr. O. W. H. Mitchell, of Syracuse, as a member of the Board of Regents Advisory Council on Health and Physical Education; Dr. Peter Irving, of New York, and Dr. H. H. Bauckus, of Buffalo, to sit on the State Nursing Council for War Service; the reappointment of Dr. George R. Critchlow, of Buffalo, as a member of the Nurse Advisory Council of the State Department of Education.

Under the topic of Office Administration and Policies, your committee notes with approval the adoption of pre-employment examinations and the maintenance of full personnel files. We should like to urge on the Council continued investigation of employee pension systems and the early adoption of some suitable action along this line.

It is interesting to note in passing the proposed changes in the bylaws and revision of the Pharmacopeia. We feel that the Medical Society of the State of New York is ably represented in this work.

Your committee approves the Council action in granting leaves of absence while in service to Drs. Wood, Peale, Retan, Rulison, Merrill, and Almour.

Your committee feels that in the remission of State assessments for members entering the armed and public health services the Medical Society of the State of New York is making a noteworthy monetary contribution to our war effort. Your committee suggests that any remission of dues allowed to women physicians be continued only if their status in the various auxiliary reserves is as physicians.

I move the adoption of this portion of the report.

....The motion was seconded.....

SPEAKER BAUER: The motion for the adoption of this portion of the report is before you. It recommends approval of the committee's actions and the Council's actions on these particular matters, but also urges that in the case of the remission of dues for women members it be only if they are acting as physicians in the war effort. Is there any discussion?

DR. JOSEPH A. GEIS, *Essex:* If I understood it right, the report said "acting as physicians in the auxiliary services." Is that correct?

DR. MONTEITH: That is right. It says, "Your committee suggests that any remission of dues allowed to women physicians be continued only if their status in the various auxiliary reserves is as physicians."

DR. GEIS: If they are in the regular services, as they are likely to be now, why not remit them too, the same as the men?

SECRETARY IRVING: That is automatic in the regular services.

SPEAKER BAUER: That would be automatic. As a matter of fact, that has already taken place, if they are in the regular services.

DR. MONTEITH: The point that the committee wished to make was that there is a possibility that women might serve in the WAACS, or the WAVES, or the rest of those alphabetical categories in other capacities than as physicians.

DR. THOMAS M. D'ANGELO, *Queens:* I don't see what difference it makes. If one of our physicians, be it man or woman, enters the service either as a physician or as a private he is serving the Army of the United States, and I don't see that it makes any difference in what capacity such a service is being rendered. His dues should be remitted if he is in the armed forces in any capacity, and the same with our women members.

SPEAKER BAUER: I think it would facilitate matters if we first moved the adoption of the report up to the point about the remission of State assessments, and then discussed that later.

DR. MONTEITH: I so move.

SPEAKER BAUER: If there is no objection, we will do that. Is there any discussion on the adoption of the report up to the question of the remission of dues?

....The question was called for, and the motion was put to a vote and was unanimously carried.....

SPEAKER BAUER: That portion of the report is adopted, and now we come to the question of the remission of dues for women members of the Society. Is there any further discussion?

PRESIDENT-ELECT MCGOLDRICK: May I ask the Secretary to let us know exactly our ruling in regard to male members of the profession and the remission of dues when in the armed services?

SECRETARY IRVING: As I understand the remission of dues for our male members, Dr. McGoldrick, as the Council has put it on the books, it is for those entering the armed forces as physicians.

TREASURER DWIGHT: I do not think so.

SPEAKER BAUER: It does not say that, but provides that remission is granted to any person, a member of the Society, who is serving in the armed forces or the Public Health Service. It does not say in what capacity.

SECRETARY IRVING: I think that is correct, sir, although our interpretation has been the other way.

PRESIDENT-ELECT MCGOLDRICK: I feel that the women physicians, particularly now that they have been granted what they desired for so long, and have practically the same standing in the armed forces as the men, would not care to have an exception made in their favor in any way, and that the same rule should apply to any member of the Society, male or female; that is, if they are engaged in the armed forces, the State assessments should be remitted.

ASSISTANT SECRETARY PODVIN: I was under the impression, Mr. Speaker, that the regulation that was adopted by the Council specified that they must possess a commission; in other words, they must be commissioned in the armed forces.

TREASURER DWIGHT: That is right.

ASSISTANT SECRETARY PODVIN: The reason for that was that the question very often arises concerning men that are serving in the Public Health Service. They are not commissioned men. They are full-time men.

SPEAKER BAUER: They are commissioned.

ASSISTANT SECRETARY PODVIN: Not all of them. We have many men in our county society who are not, and they must pay their dues.

DR. JAMES F. ROONEY, *Trustee:* It seems to me that in view of the fact that Congress has authorized the commissioning of women in the armed forces of the United States, without any specification as to whether they are going to be assigned to the Women's Army Auxiliary Corps, but with the understanding, that they may be assigned anywhere at

the objectives of the Trustees of the American Medical Association in the establishment of full-time modern health services in all areas of the country, we do not feel that the public health situation throughout New York State is in such a deplorable condition as the letter of Dr. Haven Emerson to the Council would indicate. Permissive legislation for the establishment of county health units has been in effect in New York State for over twenty years. At the present time your committee is of the opinion that it would be impossible to obtain properly qualified personnel to man county health units in the fifty-one counties of the State now without full-time county health units.

Mandatory legislation now would be fatal to the program of gradual evolution taking place under our State Department of Health. Any community that so desires may establish public health units suitable for its needs. We believe that the State Department of Health, through its district offices, through county public health committees, their nursing and clinic services, milk inspection, and allied activities are doing as much as is possible to bring to all the people the benefits of an organized public health service. Gradual evolution of the problem seems more appropriate at this time than any recommendation of suggested legislation.

Your reference committee desires in principle to endorse all efforts being made to further Public Health work throughout New York State, and to this end suggests that the matter of full-time county public health units be referred to the Council Committee on Public Health for further study and appropriate action when trained personnel for the establishment of such units becomes available.

I move the adoption of this portion of the report.

. . .The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried. . . .

DR. MONTEITH: Now I move the adoption of the report, as a whole, as amended.

. . . .The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried .

SPEAKER BAUER: Thank you, Dr. Monteith!

Section 83

Proposed Amendment to Bylaws, Chapter X, Section 1

SECRETARY IRVING: Mr. Speaker, there is in Part XII of the Council Report a matter that did not come before that reference committee, which I think should be read now. This is an amendment submitted by the Council to be acted on a year from now. I will read it. It is a small thing, so it will not take very long:

> "*Travel Expenses of Delegates to A.M.A.*—The Council recommends that Chapter X of the Bylaws be amended to allow delegates to the American Medical Association the usual travel expenses such as are allowed to members of Council, Trustees, Censors, and members of committees, instead of only 'railroad transportation and Pullman accommodations.' To that end the Council submits the following amendment:
>
> "In Chapter X, Section 1, of the Bylaws delete the sentence which reads: 'The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of such attendance shall be allowed the actual cost of railroad transportation and Pullman accommodations to the place of meeting and return.'; and insert in its place the following sentence: *'The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of such attendance shall be allowed traveling expenses.'*"

SPEAKER BAUER: This being an amendment, it will remain in the hands of the Secretary until next year when, after being duly published, it will come before you for consideration.

Section 84

Report of the Reference Committee on the Report of the Council—Part IX: Workmen's Compensation

DR. CARLTON E. WERTZ, *Erie:* Your committee urges that the duties and responsibilities and jurisdiction conferred by Workmen's Compensation Law on the medical societies, both county and State, and which the societies are eager to carry out with the object in view of assuring proper medical care to the injured or disabled worker, be maintained in the law, or in any amendment thereto that may be required as a result of the present Moreland Act investigation. Where the functions of the societies call for the investigation of any allegedly improper practices on the part of physicians, medical bureaus, or laboratories, or for hearings and trials of alleged violators of the Workmen's Compensation Law, the law should be so amended and clarified as to confer upon the societies, or their workmen's compensation boards, definite powers, such as the power to subpoena witnesses, administer the oath, and investigate the books and records of the person or bureaus charged with any violation.

The Workmen's Compensation Law should be so clarified and amended as to indicate the scope of authority of the workmen's compensation boards in reference to complaints and to indicate whether such powers apply only to complaints received by the medical societies or whether it is the function of such boards of their own initiative to seek out offenders in the first instance and bring them to trial. Only when such duties and powers are definitely defined and implemented by adequate authority can the medical society compensation boards fulfill their avowed purposes to help in a proper administration of the Workmen's Compensation Law to the end that adequate medical service be rendered at a fair and equitable cost.

We believe that the functions which were conferred by the Legislature in 1935 upon the medical societies can best be administered by organized medicine, and organized medicine has up to the present time, with limited authority, carried out these functions through the county society committees and the State Society Bureau of Compensation with zeal and vigor and with a true appreciation of the purpose of the 1935 amendments to the Workmen's Compensation Law to remove evils and abuses then existent and to prevent their recurrence.

The medical societies alone cannot be expected, despite their ability and willingness to serve as an auxiliary of the State, to remove or prevent evils, abuses, and maladministration, without a properly functioning Department of Labor, efficiently administered and properly staffed and equipped. It is, therefore, urged that any investigation of workmen's compensation practices be complete and constructive

pital, Lutheran Hospital, Midtown Hospital, West Side Hospital and Dispensary, Reconstruction Unit of Post-Graduate Hospital, Hospitals of the Department of Correction of the City of New York; and Consulting Surgeon to the Sing Sing Prison Hospital.

A man of tremendous and never-failing energy, Dr. Townsend lived a life of highest value to the health of the community, personally and through his many medical society activities. He was a clear-thinking individual who held and expounded strong convictions on the best ways for doctors to practice the healing art and to constantly improve their knowledge with the help of medical societies.

The Medical Society of the State of New York feels deeply the loss of Dr. Terry Monroe Townsend.

Mr. Speaker, I move the adoption of this memorial minute.

....The motion was seconded and was carried by the delegates arising and standing with bowed heads in silence for a minute in honor of their departed colleague.....

DR. MONTEITH: The second one:

Dr. Augustus Joseph Hambrook

Augustus J. Hambrook, M.D., of Troy, New York, died following a long illness, at the Homer Folks Hospital, Oneonta, Otsego County, New York, on July 13, 1942.

He was elected to membership in the Medical Society of the County of Rensselaer in 1909, and served as its secretary during 1912–1913. In 1928 he became a member of the Committee on Public Relations of the Medical Society of the State of New York, on which he served until 1937, when he was elected a councilor and was appointed chairman of the Council Committee on Public Relations and Economics, in which capacity he served the State Society until his demise.

In 1933 and 1934 he was second vice-president of the Third District Branch and in 1935 and 1936 became its president. During these years he also was a censor of the State Society. In 1937 he was a member of the Committee on Trends in Medical Practice and also of the Committee to Confer with the State Hospital Association. The next year he served on the Council Committee on Contacts with the Health and Welfare Departments of the State while at the same time acting as chairman, during that year, of the Council Committee on the Deaf and Hard of Hearing. In 1942 he also acted as a member of the Joint Committee on Dental Health of the State Medical and State Dental Societies.

He was a graduate of Albany Medical College, and during the first World War was a captain in the Medical Corps, U.S. Army.

The Medical Society of the State of New York suffered a great loss in the death of this valuable councilor.

I move the adoption of this memorial minute.

....The motion was seconded and was carried by the delegates arising and standing with bowed heads in silence for a minute in honor of their departed colleague.....

DR. MONTEITH: The third one:

Dr. Grant Charles Madill

Dr. Grant Charles Madill, of Ogdensburg, served the Medical Society of the State of New York over many years until his death in his seventy-ninth year on March 26, 1943. Elected to membership by the St. Lawrence County Medical Society in 1906, he had been a very active worker in county and State societies.

Dr. Madill was president of the Fourth District Branch of the Medical Society of the State of New York in 1911 and 1912; President of the Medical Society of the State of New York, 1919–1920; Delegate to the American Medical Association before and after his presidency for many years. He was a Trustee of the State Medical Society from 1926 to 1935.

Dr. Madill secured his M.D. from Bellevue Medical College in 1886, and interned at Presbyterian Hospital in New York 1886–1888, and then started his long practice in Ogdensburg.

In 1908 he was given the degree of LL.D. by St. Lawrence University, and in 1932 the same degree by New York University. Long interested in medical education, Dr. Madill was a Regent of the University of the State of New York for years and active in that capacity at the time of his death.

Dr. Madill was a Fellow of the American College of Surgeons, and Chief Surgeon, of long standing, at the A. Barton Hepburn Hospital in Ogdensburg.

The death of Dr. Grant Charles Madill was a great loss to the Medical Society of the State of New York and to the State of New York.

I move the adoption of this memorial minute.

....The motion was seconded and was carried by the delegates arising and standing with bowed heads in silence for a minute in honor of their departed colleague.....

DR. MONTEITH: In regard to the report of the Council Advisory Committee to the Woman's Auxiliary, your reference committee desires to endorse approval of the work of the Woman's Auxiliary. We realize that situations contingent on wartime restrictions are limiting the activities of the Auxiliary in some ways, but we urge upon them the continuance of all possible projects at this time especially in the fields of health insurance and matters of health education.

I move the adoption of this portion of the report.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

DR. MONTEITH: *Chiropractic Study*—Your reference committee heartily endorses the suggestion of the Council to appoint a subcommittee of the Council Committee on Legislation to prepare to attend hearings of the Legislative Commission which has been set up to study the subject of chiropractic. In order properly to emphasize by the House of Delegates such action, and in order to lend the full weight of the Medical Society of the State of New York to the work of such a body, your reference committee recommends that the House of Delegates approve that there be appointed a subcommittee of the Council Committee on Legislation to attend meetings of this Legislative Commission.

I move the adoption of this portion of the report.

....The motion was seconded.....

SPEAKER BAUER: You have this portion of the report before you for adoption. In substance you really approved it yesterday in connection with the *Basic Science Law*. Is there any discussion on it?

....The question was called for, and the motion was put to a vote and was unanimously carried.....

DR. MONTEITH: *County Health Units*—While your reference committee is in deepest accord with

1. Litigation.—For the reporting period 120 cases were instituted and 164 cases disposed of as follows:

Settled—48 cases
Terminated in favor of the defendant—111 cases
Judgment for the plaintiff—5 cases

On January 31, 1943, there were pending 369 cases as compared with 413 cases as of January 31, 1942.

The membership is again cautioned against careless, hasty, and unjustified criticism by one physician of the work of another. This often leads to malpractice action. The hazard of such malpractice action is also called to the attention of the members inasmuch as the rights of the physician in these actions are in the hands of lay jurors, and verdicts are frequently rendered where sympathy, passion, and prejudice or bias are responsible for the verdict.

The Council again recommends the loyal support of every member of the Society for the Group Plan of Insurance, which has been in operation for twenty years and has set a record.

Your reference committee endorses this recommendation. We understand that approximately 50 per cent of the members (this figure is on the verbal information by Dr. Bandler) carry the Group Plan Insurance, and we urge the rest of the members to join the Plan.

Appreciation for cooperation with the Counsel is extended to the Yorkshire Indemnity Company and its claim agent, Mr. Horace Crowell, Jr., to the Council Committee, Dr. Bandler, chairman, to the Counsel associates, Mr. William F. Martin and Mr. Thomas H. Clearwater, and to the Counsel's entire staff both legal and clerical.

2. Counsel Work and Activities.—The Counsel has prepared articles in the nature of editorial comment for the NEW YORK STATE JOURNAL OF MEDICINE; also a number of inquiries and answers relating to the legal questions in medicine.

Acting with the Committee on Constitution and Bylaws, the Counsel examined proposed amendments to the constitution and bylaws of a number of component county societies and has rendered advice and made suggestions in connection therewith.

The Counsel drew the contract between the Society and the late Mr. Lighty with reference to the advertising matter in the NEW YORK STATE JOURNAL OF MEDICINE and the *Medical Directory* and the commercial exhibits. The Counsel drew the contract between the Society and Dr. Joseph S. Lawrence, Executive Director; also the contract with Mr. Dwight Anderson as director of the Public Relations Bureau and business manager of the NEW YORK STATE JOURNAL OF MEDICINE and *Medical Directory.*

The Counsel has attended and advised at all meetings of the Council of the Society and meetings of its various committees.

3. Legislative Advice and Activities.—During the 1942–1943 session of the New York State Legislature, the Counsel examined problems affecting the medical profession and gave advice with reference thereto. He also conferred with the Executive Director of the Society. Mr. Clearwater has attended the annual conference of the Council Committee on Legislation and the Chairmen of the County Societies' Legislative Committees held at Albany.

I move the adoption of this portion of the report.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

DR. KRAKOW: The report just referred to was prepared and signed by our late Counsel, Mr. Lorenz Joseph Brosnan, whose untimely death occurred on the twelfth of April, 1943, and the Council Committee on Malpractice Defense and Insurance presents the following memorial, drawn up after his death:

"Lorenz Joseph Brosnan died on April 12, 1943, after a brief illness. Mr. Brosnan had served the Medical Society of the State of New York as Counsel since 1930 and had fulfilled every expectation of that position with a competency second to none. Prior to his designation as Counsel, Mr. Brosnan had been associated with Lloyd Paul Stryker, his immediate predecessor.

"Lorenz Brosnan was born in New York City in 1894 and had attended De La Salle Institute. He was graduated from Manhattan College in 1915 with the degree of A.B. and in 1918 was graduated from the Law School of Columbia University and shortly thereafter was admitted to the Bar. During the thirteen years that Mr. Brosnan served our Society as Counsel he rendered most exacting and varied services, all of which were faithfully performed. His annual report for the year 1942 has just been presented to this House of Delegates and, as always, reveals his vast accomplishments for the good of our organization.

"Mr. Brosnan was a member of the Association of the Bar of the City of New York, the New York County Lawyers Association, the New York State and the American Bar Associations, the Archbishop's Committee of the Laity for Catholic Charities, the Xavier Alumni Sodality, the Manhattan College Alumni Society, the Knights of Columbus, the Society of the Friendly Sons of St. Patrick, the Catholic Club, the Manhattan Club, and the Larchmont Shore Club.

"Lorenz Brosnan is survived by his widow, his four daughters, and two sons. Also surviving are two brothers, John F. Brosnan, a member of the New York Bar, and Captain Vincent J. Brosnan, Catholic Chaplain of the Army of the United States, stationed at Camp Livingston, Louisiana. To all of them the sincerest sympathy and heartfelt condolence of this House of Delegates are extended, and be it recorded that this expression of our deep sense of loss is placed in our minutes and that a copy be transmitted to the family."

I move the adoption of this portion of the report.

....The motion was seconded.....

SPEAKER BAUER: You have before you for the adoption of this portion of the report which consists of a memorial minute to one who for thirteen years was Counsel of the State Society, and who died this past month.

DR. JAMES F. ROONEY, *Trustee:* Briefly, I should like to say something more than this memorial does about Mr. Brosnan. It has been my opportunity for the past eight or ten years to have heard from many justices of the Supreme Court of the State of New York concerning Mr. Brosnan's ability and the credit that he reflected upon this Society as contrasted with some of the unfortunate instances we had had earlier in our career.

I should like to take this moment to pay my own personal tribute to Lorenz Brosnan, one of my best friends, and I think one of the best friends this Society ever had in the legal profession.

SPEAKER BAUER: Thank you, Dr. Rooney!

....The delegates arose and stood with bowed

and involve all parties to the functioning of the law with whom injured workers come in contact from the very inception of their injuries or claims to the adjudication of same by the various branches of the Labor Department, including the claim representatives, insurance carriers, or employers' representatives or organizations. During the past seven years our Workmen's Compensation Bureau has made numerous recommendations for changes in procedure and for additional legislation and has called attention to procedures requiring change—all in the interest of a better functioning of the Workmen's Compensation Law.

The social benefits conferred upon our people by the Workmen's Compensation Law should not be nullified or diminished by ambiguities in the law or maladministration or dishonesty on the part of anyone. The organized medical profession has always maintained a high standard of ethical and professional conduct, and will continue to do so. It is willing and eager to punish any physicians who have been false to these ideals or unmindful of their responsibilities toward the injured worker. It has always been the ideal of our workmen's compensation committees and of the Workmen's Compensation Bureau to function with these ideals in mind. We therefore urge serious consideration by our legislative bodies of the present inadequacies of the law and the addition of such amendments as will strengthen it. In this procedure the Medical Society of the State of New York stands ready to give a full measure of help and cooperation, and we, therefore, recommend that this matter be referred to the Legislative Committee of the State Medical Society, and that they be instructed to cooperate with the Workmen's Compensation Board to secure the proper legislation to accomplish the above recommendation.

Your reference committee approves the report of the Workmen's Compensation Committee completely, especially wishes to stress the section in regard to radiology ratings, and recommends the increased use of examining boards for such ratings. We also agree that the granting of specialty ratings in the other specialties must, too, be based on high standards. The section on ratings of the refugee physicians is of particular importance. His or her ability should be definitely established before granting the specialist's rating.

The committee also recommends that because of the many and various duties of our Workmen's Compensation Bureau and the many demands made upon it, and with the needed increased attention to the Workmen's Compensation Law and necessary amendments to the same, there be the employment of a full-time Medical Director.

I move the adoption of the committee's report which is signed by Carlton E. Wertz, chairman, Roy B. Henline, Charles S. Lakeman, Milton S. Lloyd, and George C. Vogt.

....The motion was seconded.....

SPEAKER BAUER: You have before you the report of the reference committee, which approves in substance the work of the Council Committee on Workmen's Compensation. The final recommendation was acted upon yesterday. Is there any discussion on the report as a whole?

....The question was called for, and the motion was put to a vote and was unanimously carried.....

SPEAKER BAUER: Thank you, Dr. Wertz!

Section 85. (Sec 14)

Report of Reference Committee on the Report of the Council—Part XIII: Malpractice Defense and Insurance and Legal Counsel

Malpractice Defense and Insurance. DR. MOSES H. KRAKOW, *Bronx:* Your reference committee has reviewed the report of the Committee on Malpractice Defense and Insurance and notes that the following changes were made in the Group Insurance Contract:

1. On recommendation of the Committee on Malpractice Defense and Insurance, the Council of the Society on April 28, 1942, approved an increase in the base rate to $32—an increase of $4. No increase in the excess limit rates was necessary.

2. An additional surcharge of 50 per cent of the premium for "cosmetic plastic surgery" was adopted.

Arrangement was made with the carrier, the Yorkshire Indemnity Company, for a reduction of 50 per cent in the annual premium for doctors serving in the military forces of the United States, effective November 1, 1942. The insured doctor upon entering the military services may obtain this reduction, provided the insurance is limited to claims and suits arising out of the professional services rendered to persons in the armed forces of the United States or, in emergency, to civilian patients. Coverage is also extended to liability of the insured for action arising out of the appointment by him of another physician to substitute for him in private practice while he is in the armed forces, providing the substitute physician is a member of the Medical Society of the State of New York and is individually insured in the Group Plan of the Society.

Your reference committee urges all physicians entering the military service to retain their Malpractice Insurance in the Society's Group Plan. However, the committee feels that physicians in the armed forces of the United States or serving in any capacity for the Selective Service or Induction Boards should not be held financially responsible for any judgment resulting from any court action for malpractice when such treatment or examination has taken place in the course of their duties.

Your reference committee recommends that the Council of the Medical Society of the State of New York initiate the necessary measures for the accomplishment of this.

The attention of the members practicing x-ray therapy exclusively is called to the special annual base premium of $30.

The report is concluded by emphasis on the fact that the Yorkshire Indemnity Company is a New York State corporation, completely under the jurisdiction of the State Superintendent of Insurance, who has stated that "all of their assets are held within the United States."

I move the adoption of this report.

....The motion was seconded.....

SPEAKER BAUER: You have before you the report of the Reference Committee on Malpractice Defense and Insurance. It carries a specific recommendation at the end: that the Council should take action to protect members in the armed forces from being subject to suits for malpractice in military service and selective service. Is there any discussion?

....The question was called for, and the motion was put to a vote and was unanimously carried.....

Report of the Legal Counsel. DR. KRAKOW: The report of the Counsel is for the period of February 1, 1942, to January 31, 1943, and is given under three main divisions: (1) litigation; (2) counsel work and activities; and (3) legislative advice and activities.

Service. This is along the same line that we discussed a while ago in connection with members in the military services. Is there any discussion?

DR. JAMES F. ROONEY, *Trustee:* I am not so sure that it is a wise policy for this Society to grant the same privileges to those men who enter the Veterans' Facility as we have already granted to those who are in the armed forces of the United States.

I think all of you will have noted that the resolution says in effect for those men who have entered the Veterans' Facility for temporary duty. They are not members of the armed forces. They are employed by contract with the government, and they are in exactly the same status as contract surgeons, but with less of the military privileges and with no rank.

I am loath to think that, perhaps, there are some members of the medical profession who may be perfectly willing to enter into, and accept a temporarily exempted status with, the Veterans' Facility rather than to take their commission in the armed forces of the United States.

I feel that if we adopt this resolution we are going too far, and I personally hope that it will not prevail.

SPEAKER BAUER: Is there any further discussion?

DR. JOHN J. BUETTNER, *Onondaga:* The reason for introducing this resolution was that one of our members who could not get into the armed forces was able to get into the Veterans' Administration Facility, and he asked to have his dues remitted. The county society remitted his dues. The State Society did not. As it stands at the present time, in order to keep him in good standing in the State Society the county society would have to pay his dues. We are, therefore, asking, in this particular case, for a man who could not get into the armed services but who did enter the Veterans' Administration Facility that his dues be remitted.

DR. ABRAHAM KOPLOWITZ, *Kings:* I should like to offer an amendment providing that the doctor is either above the age for the armed services or has been rejected.

....The motion was seconded.....

SPEAKER BAUER: It has been moved and seconded that the motion be amended by adding to it that the dues of a person entering the Veterans' Service for the duration be remitted provided he is above the age for military service or has been physically rejected for military service.

DR. CHARLES F. MCCARTY, *Kings:* I should like to ask how we are going to find that out. That would be almost impossible to find out.

I should also like to inquire whether we are going to inform all of the doctors who take government civil service jobs at the present time that their dues are remitted and that they have exactly the same status in that respect as those men who go into the Veterans' Bureau who are not in the military service—namely, full remission of their dues as the men in the Army, Navy, and the United States Public Health Service now enjoy for the duration?

PRESIDENT-ELECT MCGOLDRICK: I should like to add a word to Dr. Rooney's and Dr. McCarty's statements. In the first place, this is a request to overrule the action of the Council and make a mandatory order by this body on the Council. We have the rules adopted last year and confirmed so far that the proper mode of action is for the county society to make its request of the State Society through the Council, and their action has up to now been final, and approved at the end of the year by the House of Delegates.

In the first place this would overrule that, and would order special action in this particular group of doctors. The Veterans' Administration continues all the year round. We know there have been many abuses in the Veterans' Bureau since the last war. We know that many doctors have been in it for years without any relation to the war effort or any special patriotic motive except the objective of a doctor in doing his best work for individuals. It may continue and will continue, after the war. It does not involve any war risk. A man may leave it at any moment when his contract expires. It is an optional matter with him. Therefore, I feel it is contrary to the spirit we have had here shown: that the men and women in the armed forces and working for their country are the ones that should have their dues remitted. While the Veterans' Facility is, perhaps, an allied arm, it is not really the armed forces.

SPEAKER BAUER: The question is on the amendment: Shall we add the provision as to age and physical disqualification? Is there any discussion?

DR. KOPLOWITZ: I desire to withdraw that amendment.

SPEAKER BAUER: If there is no objection that amendment will be withdrawn. Hearing none, it is withdrawn, and we come back to the original motion: Shall the dues of men in the Veterans' Service be remitted for the duration?

... The question was called for, and the motion was put to a vote and was lost.....

DR. CARROLL: That completes our report.

SPEAKER BAUER: Thank you, Dr. Carroll!

Dr. Swift, have you any further resolutions?

DR. SWIFT: No.

SPEAKER BAUER: Dr. Masterson, how about New Business A?

DR. MASTERSON: There is one more resolution.

SPEAKER BAUER: Is there any new business to come before the House in the meantime?

Section 89

Proposed Amendment to Bylaws, Chapter II, Section 1

DR. ALBERT A. CINELLI, *New York:* This is an amendment to the Bylaws of the Medical Society of the State of New York, Chapter II, Section 1. Under (c) which now reads:

> "Each component county society shall be entitled to elect as many delegates as there shall be State Assembly Districts in each county at the time of the election, but each component county medical society shall be entitled to elect at least one delegate"

is to be amended to read:

> *"Each component county society shall be entitled to elect delegates in proportion to the number of doctors practicing in the county at the time of election, but each component medical society shall be entitled to elect at least one delegate."*

DR. HORACE E. AYERS, *New York:* I second that.

SPEAKER BAUER: There was an amendment introduced yesterday to the same article. This will remain in the hands of the Secretary for one year, when, after being duly published, it will come before you for consideration.

Section 90

Announcements

SPEAKER BAUER: I have a few announcements to make. The tickets for the Civilian Defense Din-

heads for a minute in silence in honor of Lorenz Joseph Brosnan.....

DR. KRAKOW: I move the adoption of the report of your reference committee, consisting of Moses H. Krakow, chairman, Benjamin M. Bernstein, Samuel E. Appel, John Dugan, and Denver M. Vickers, as a whole.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

Section 86

Report of the Reference Committee on Report of the Council—Part XI: Status of Foreign Physicians

DR. LEO F. SIMPSON, *Monroe:* Your reference committee has carefully considered the recommendations of the Subcommittee on the Status of Foreign Physicians, which have been adopted by the Council and adds its endorsement to that of the Council.

We have, in addition, studied the complementary article published by this committee in the NEW YORK STATE JOURNAL OF MEDICINE of January 15, 1943, under the title of "Status of Foreign Physicians."

As a result of this study, your committee makes the following recommendations:

1. We recommend that the House of Delegates of the Medical Society of the State of New York urge the Board of Regents of the State of New York to refuse, in the future, to admit to examination for licensure any graduate of a foreign medical school, 25 or more per cent of whose graduates taking the examination during the past ten years have failed to pass. This percentage is to be based on the average of the results of the individual years.
2. That the House of Delegates of the Medical Society of the State of New York urge the Board of Regents of the State of New York to limit definitely to three in all the number of examinations that may be taken by any candidate for licensure to practice medicine. Your committee feels that if a candidate cannot pass these examinations after three attempts, it clearly indicates a medical education of a very inferior quality, and one against which the people of New York State should be adequately protected.
3. We recommend the appointment of a continuing committee by the President to be known as the "Committee on Medical Licensure," whose duties shall be to compile, study, and assay such pertinent data as may be of assistance to the Board of Regents to the end that the people of the State of New York be guaranteed physicians of the highest quality on whom they can rely with full confidence.

I move the adoption of the report of this committee, consisting of Leo F. Simpson, chairman, Joseph C. O'Gorman, Maurice J. Dattelbaum, Stephen H. Curtis, and Beverly C. Smith.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

Section 87

Report of the Reference Committee on Report of the Council—Part V: Medical Expense Indemnity Insurance

DR. HARRY S. BULL, *Cayuga:* Your Committee on Report of the Council, Part V, has carefully reviewed the report as published in your JOURNAL. We note with pleasure that there has been progress in this field during the past year; that the principle of voluntary premedical care, sponsored by organized medicine, is being more generally accepted; that it has not been widely accepted has been due in part to many problems: the necessity of replacing the older plans by new contracts; the readjustment of fee schedules, and possibly to lack of interest of members of the profession in localities where the idea of such insurance is new and untried, and, perhaps, in part to the timidity on the part of the professional man to sell this idea to the public.

Your committee appreciates the large amount of time and effort which has been put forward by the committee and its metropolitan subcommittee in attempting to further this project. We would congratulate them on the work already accomplished and would respectfully recommend to this House that these committees be continued to further advance this plan in the year to come.

That is respectfully submitted by the reference committee consisting of Harry S. Bull, chairman, Robert F. Barber, Ada C. Reid, Alfred H. Noehren, and Nelson W. Strohm. *I move its adoption.*

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

Section 88. (See 44)

Report of Reference Committee on New Business C—Remission of Dues of Members Serving in Veterans Administration Facility

DR. JOHN D. CARROLL, *Rensselaer:* On the resolution presented by Dr. John J. Buettner, of the Onondaga County Society, concerning the remission of dues and assessments of members of the county societies who are enrolled in the Veterans Administration Facility, reading:

"WHEREAS, at a recent meeting of the Comitia Minora the motion was passed that the delegates to the Annual State Meeting, soon to be held in Buffalo, be instructed to present a resolution to the House of Delegates that the dues and assessments of members of county societies who are enrolled in the Veterans Administration Facility for the duration be remitted while they are temporarily removed from active civilian practice, in the same manner as those members in the United States Public Health Service.

"The reason prompting this action is the fact that one of our members has gone into the Veterans Administration Facility for the duration, and we have carried on considerable correspondence in the hope of having his dues and assessments remitted, only to find that this is not possible unless the House of Delegates takes some action at their coming meeting.

"The Comitia Minora, with the approval of the Onondaga County Medical Society, requests that their delegates introduce the following resolution at the coming meeting of the Medical Society of the State of New York; therefore, be it

"*Resolved*, that members of component county medical societies entering the Veterans Administration Facility on a temporary basis have their dues remitted for the duration."

Your committee recommends the approval of this resolution, and I move the adoption of this part of the report.

.. The motion was seconded.. ..

SPEAKER BAUER: The resolution is before you to permit remission of dues for persons in the Veterans

TELLERS

SPEAKER BAUER: The Chair will appoint the following fifteen men as tellers:

Charles F. McCarty, *Kings*, Chairman
Edgar Bieber, *Chautauqua*
Chester O. Davison, *Dutchess*
John C. Brady, *Erie*
Herbert E. Wells, *Erie*
Fred C. Sabin, *Herkimer*
Leo S. Schwartz, *Kings*
Francis N. Kimball, *New York*
Samuel M. Kaufman, *New York*
Henry W. Miller, *Putnam*
Ezra A. Wolff, *Queens*
Laurance D. Redway, *Westchester*
Charles C. Trembley, *Franklin*
Charles A. Prudhon, *Jefferson*
John J. Gainey, *Kings*

NOMINATIONS AND ROLL CALL

Nominations were then called for and received. ....The assistant secretary called the roll and the following were accounted for:

James F. Rooney

ner this evening can be secured at the registration desk. Everyone is welcome.

Now, gentlemen, a few words about this afternoon's session: As you know, the election comes this afternoon. We have a very full afternoon. Not only must the House complete its business but there is a meeting of the Society, a general session, and I am afraid things are going to be jammed up, so we want to get through as quickly as we can. I think we will have cleared up all the business by the time we adjourn this morning except the election. The election has been called for 1:00 P.M. The only way the time could be advanced would be by a two-thirds vote. Inasmuch as it has already been announced as an order of business I question whether we could have people get here much before that, but please be here at least at 12:45 P.M. so we can start promptly at 1:00 P.M.

There is another little innovation this afternoon. In previous years, up to last year, the roll has been called twice: once at the opening of the session and once when you voted, and still we never had much of an idea as to who voted and who did not. This year, as you come in the door, you will be checked off, so that will take a little time. Therefore, please try to get here before 1:00 P.M. As the roll is called for voting, your name again will be checked at the ballot box. In that way we will have direct knowledge of those who are present and those who vote. The only thing we will not know is how you vote. (Laughter) Please be here promptly at 12:45 P.M. so that we can get the election out of the way.

Another innovation that we will introduce is that last year, if you will recall, we were held up for about half an hour, and delayed the general session, waiting for the report of the tellers. The Bylaws provide that the Speaker shall appoint tellers but do not say how many. We have always heretofore appointed five. This year I am going to appoint fifteen so that they can do their work a great deal faster. (Laughter) There will be seven groups of two men instead of two groups of two men, and the chairman. I will announce the tellers at the beginning of the session, and I hope all of you will be here. Particularly those of you who have not been on committees are going to be elected tellers, so everybody try to be here between 12:30 and 12:45 P.M. so we can start the minute of 1:00 P.M.

We will have a recess of five minutes while waiting for the report on the one resolution that is to come from New Business Committee A.

....There was a short recess taken at this point...

SPEAKER BAUER: Please come to order, gentlemen. The Chair recognizes Dr. Masterson, chairman of New Business Committee A.

Section 91. (*See 28*)

Report of Reference Committee on New Business

A—Blood and Plasma Exchange Bank

This is on the resolution introduced by Dr. Kenney, of New York, concerning the Blood and Plasma Exchange Bank, and reads:

"WHEREAS, the Medical Society of the County of New York, under the leadership of its Special Committee on Blood Transfusion, is sponsoring a nonprofit organization known as the Blood and Plasma Exchange Bank; and

"WHEREAS, this organization has been approved by the Greater New York Hospital Association; and

"WHEREAS, the Blood and Plasma Exchange Bank has put into effect in the County of New York a uniform procedure of the highest standards for blood banks organized within the hospitals; and

"WHEREAS, the Blood and Plasma Exchange Bank is making available to patients blood and plasma, both fluid and dried, at reduced cost for those who can and wish to pay, and free of charge to those who can only supply blood; and

"WHEREAS, the Blood and Plasma Exchange Bank is storing up a reserve of plasma to be used in the event of a catastrophe; and

"WHEREAS, organized medicine is not only rendering these benefits to the sick, but also retaining for members of the profession the practice of transfusion and the art of preparing plasma within the present hospital system; therefore be it

"*Resolved*, that the Medical Society of the State of New York sponsor the extension of the activities of Blood and Plasma Exchange Banks throughout the State, with the view toward assisting and encouraging Blood and Plasma Exchange Banks to extend to the sick throughout the State, and even to our remotest communities, the benefits they are now rendering; and further be it

"*Resolved*, that the Medical Society of the State of New York refer this matter to a Council Committee or a Special Committtee on Blood Transfusion to accomplish these aims."

Recommendation: The committee approves of this resolution, and moves its adoption.

....The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.....

SPEAKER BAUER: Thank you, Dr. Masterson!

Dr. Clemmons, the Procurement and Assignment Chairman, is here in his bailiwick and will be glad to see any of you who have problems to take up with him.

It has been my experience, that you can consume liquor quicker than food in this hotel, so I suggest you eat first and have your cocktails later, so you can get here promptly.

We will now stand in recess until 1:00 P.M., but please be here at least by 1:00 P.M. because we are going to start then, and no fooling!

....The session recessed at 11:15 A.M.....

Afternoon Session

Tuesday, May 4, 1943

The session convened at 1:00 P.M.

SPEAKER BAUER: The House will be in order.

Section 92

Elections

....Announcements were made that meetings of the Council and the Trustees would be held later in the afternoon, and that Dr. Clemmons would be glad to see any of the committee chairmen at the booth of the Procurement and Assignment Service.....

SPEAKER BAUER: The first order of business is the election of officers. I will announce that there are 162 members of the House of Delegates, both officers and delegates, present. That is a pretty good attendance.

SPECIAL MENTION

To the Army Museum for timely and comprehensive charts on tropical diseases.

The committee feels that all these exhibits, as well as many other worthy demonstrations, merit close scrutiny by members of the profession.

SPEAKER BAUER: I wish to extend to you and your subcommittee our thanks for your work, and to compliment these gentlemen on their well-earned awards.

Section 95

Tribute to Dr. Robert Brittain

SPEAKER BAUER: There is one delegate in this House to whom I think we should pay tribute this morning. He has just cast his ballot for the fifty-first time in this House of Delegates. That is something for the younger generation to shoot at. I will ask Dr. Brittain to arise so we can applaud him. (Applause)

Section 96

Speaker's Appointments to Planning Committee for Medical Policies

SPEAKER BAUER: Yesterday you approved a resolution for the appointment of a committee on long range planning to consist of eleven members, six of whom were to be appointed by the Speaker, the other five to be certain officers of the Society—namely, the President, who next year will be Dr. McGoldrick; the President-Elect, Dr. Bauckus, whom you have just elected; the Secretary, Dr. Irving; the Speaker; and either the Chairman of the Board of Trustees or a member whom he may designate. The Board of Trustees meets this afternoon to elect its chairman, and we will have the name of that man later.

The six men to be appointed by the Speaker are as follows: George W. Cottis, Chautauqua County; Norman S. Moore, Tompkins County; Walter W. Mott, Westchester County; J. Stanley Kenney, New York County; Leo F. Simpson, Monroe County; Herman G. Weiskotten, Onondaga County.

Section 97

Greetings from Waldorf-Astoria, New York

SECRETARY IRVING: Mr. Speaker, I have here a telegram from the Convention Manager of the Waldorf-Astoria Hotel, reading:

> "The management of the Waldorf-Astoria extends best wishes for a successful and constructive meeting. Kindest regards.
>
> J. P. Hoenig, Director of Sales."

Section 98

Presentation of Incoming President-Elect, Dr. Herbert H. Bauckus, to the House

SPEAKER BAUER: Dr. Trick, will you seek out the new President-Elect of the Medical Society of the State of New York, and escort him to the platform?

....Dr. Harry R. Trick escorted Dr. Herbert H. Bauckus to the platform amid applause.....

SPEAKER BAUER: Gentlemen, I present to you your next President-Elect, Dr. Bauckus.

DR. BAUCKUS: Mr. Speaker and Members of the House, you have very generously given me your highest honor, and by that action you have brought great distinction to Erie County. I recognize that, yet I lack the words adequately to express to you my thanks and appreciation for it.

I have had the experience in this past year of working with Dr. Cottis, and I know that I will gain a great deal more benefit from the capable leadership of Dr. McGoldrick in the ensuing year. My association with the members of the House and with the officers will do a great deal to help season me, so that when it becomes my duty to carry on I shall be able to do it with a certain amount of credit to you and I hope to myself.

I know that there are older and wiser and more experienced men and women in the Medical Society of the State of New York, and I shall not forget that.

One of these years we will have a victory year. We hope it will be this year, and that it will be as soon as possible. That victory year will have to be followed by the important work of reconstruction. Both tasks are very important to the American people, and it is most necessary that the medical profession, especially organized medicine, take its part in the development of a good future for all of us.

Again I sincerely thank you very much indeed. (Applause)

SPEAKER BAUER: Thank you, Dr. Bauckus!

Section 99

Presentation of Incoming Second Vice-President, Dr. Norman S. Moore, to the House

SPEAKER BAUER: Dr. Booth will you seek out the gentleman whom we have just elected as Vice-President and escort him to the platform—Dr. Norman S. Moore?

....Dr. Arthur W. Booth escorted Dr. Norman S. Moore to the platform amid applause.....

DR. BOOTH: Mr. Speaker and Members, I present Dr. Moore. (Applause)

SPEAKER BAUER: Delegates, I give you the new Second Vice-President of the Medical Society of the State of New York, Dr. Moore.

DR. MOORE: Members of the House of Delegates, I am overcome by the vote of confidence which you have expressed in Central New York and in me. As I am the baby of the slate, I feel that I should say no more and take lessons from my elders. (Applause)

Section 100

Vote of Thanks to Arrangements Committee

SPEAKER BAUER: Gentlemen, I think it would be very timely indeed if someone would propose a motion of thanks to the Arrangements Subcommittee, both general and local, for their untiring efforts in making this meeting so successful.

....The motion was made from all sides of the room.....

SPEAKER BAUER: It seems to be moved by at least half a dozen people. I am sure we need no discussion on that, and I will ask you to vote by giving a rising vote of thanks to them.

....The delegates arose and applauded.....

Section 101

Vote of Thanks to Scientific Program Committee

DR. ALBERT F. R. ANDRESEN, *Kings:* I should like to propose a vote of thanks to the Scientific Program Subcommittee, Dr. Dexter Davis and his committee, for the excellent scientific program they have prepared for us.

SPEAKER BAUER: I am sure that also needs no discussion. I will put the question to you at once.

EX-PRESIDENTS

James F. Rooney (voted as Trustee)
Arthur W. Booth
Nathan V. Van Etten
Harry R. Trick
William H. Ross (voted as Trustee)
William D. Johnson
Chas. Gordon Heyd
Arthur J. Bedell
Floyd S. Winslow (voted as Councilor)
William A. Groat
James M. Flynn
Samuel J. Kopetzky (voted as Officer)

ELECTION OF OFFICERS, TRUSTEES, AND COUNCILORS

The following officers were elected:
President, Thomas A. McGoldrick, *Brooklyn*
President-Elect and
First Vice-President, Herbert H. Bauckus, *Buffalo*
Second Vice-President, Norman S. Moore, *Ithaca*
Secretary, Peter Irving, *New York*
Assistant Secretary, Edward C. Podvin, *Bronx*
Treasurer, Kirby Dwight, *New York*
Assistant Treasurer, James R. Reuling, Jr., *Bayside*
Speaker, Louis H. Bauer, *Hempstead*
Vice-Speaker, William Hale, *Utica*

The following trustee was elected for a five-year term ending 1948:

Edward R. Cunniffe, *Bronx*

The following Councilors were elected for a three-year term ending 1946:

Charles M. Allaben, *Binghamton*
Ralph T. Todd, *Tarrytown*
Carlton E. Wertz, *Buffalo*

ELECTION OF A.M.A. DELEGATES

The following were elected 1944–1945 delegates: Louis H. Bauer, *Hempstead;* James M. Flynn, *Rochester;* J. Stanley Kenney, *New York;* George W. Kosmak, *New York;* John J. Masterson, *Brooklyn;* Thomas A. McGoldrick, *Brooklyn;* Walter W. Mott, *White Plains;* F. Leslie Sullivan, *Scotia;* Louis A. Van Kleeck, *Manhasset.*

The following were elected 1944–1945 alternate delegates: David W. Beard, *Cobleskill;* Thomas M. D'Angelo, *Jackson Heights;* Edward P. Flood, *Bronx;* William Hale, *Utica;* B. Wallace Hamilton, *New York;* Moses H. Krakow, *Bronx;* Stephen R. Monteith, *Nyack;* Scott L. Smith, *Poughkeepsie;* Moses A. Stivers, *Middletown.*

ELECTION OF RETIRED MEMBERS

The following members were elected to Retired Membership:

S. Josephine Baker, *Belle Mead, N.J.*
Lyman G. Barton, *Plattsburg*
Frank V. Brownell, *Canajoharie*
Frank T. Carmer, *Newfane*
Arthur S. Chittenden, *Washington, D.C.*
Samuel W. Close, *Gouverneur*
Samuel Cochran, *New York*
Halsey E. Cooley, *Wellsville*
William C. Couch, *Watertown*
Walter Gray Crump, *New York*
Louis M. Dusseldorf, *Brooklyn*
Paul G. Frank, *Kew Gardens*
Homer E. Fraser, *New Lebanon*
Emma C. Gibbons, *Rochester*
Charles Graef, *Bronx*
John H. Gutmann, *Albany*
James T. Hardy, *Brooklyn*
Moses Harwich, *New York*
Hiram B. Hawley, *Syracuse*
Henry A. Hoyt, *Watertown*
Lee Maidment Hurd, *Rowayton, Conn.*
George T. Imrie, *Rochester*
Robert F. Ives, *Brooklyn*
Nehemiah Janko, *New York*
Jerome Kingsbury, *New York*
Henry L. Kreis, *Brooklyn*
Eli Long, *New York*
Lewis Henry Marks, *Poughkeepsie*
I. Julius Martinson, *New York*
Frank C. Matthews, *Bronx*
William Moser, *Brooklyn*
Thomas F. Patterson, *Brooklyn*
Paul J. Rosenheim, *New York*
Harry Projector, *Washington, D.C.*
Benjamin L. Schaeffer, *South Harwich, Mass.*
George D. Scott, *New York*
Charles J. Search, *Brooklyn*
Charles R. Seymour, *Binghamton*
Joseph P. Sheridan, *Richmond Hill*
J. Gorse Simmons, *Bronx*
William Steinach, *New York*
Binford Throne, *Anna Marie, Fla*
Henry Wahn, *Bronx*
John E. Welch, *New York*

SPEAKER BAUER: I wish to thank you for your patience with your presiding officer and for your expression of renewed confidence in him. They say if anything happens once, it is an accident; twice, a coincidence; three times, a habit; but what the hell four times is I don't know.

Section 93

Report of Committee on Prize Essays

DR. CHAS. GORDON HEYD: Mr. Chairman and Members of the House of Delegates, only one essay was submitted this year, and in the opinion of the Prize Essay Committee it did not warrant the award of the prize, so no award is made this year.

Section 94

Report of Committee on Awards for Scientific Exhibits

SPEAKER BAUER: The Chair will now hear from Dr. Dickson, chairman of the Subcommittee on Scientific Exhibit Awards of the Convention Committee.

DR. ELTON R. DICKSON: The Subcommittee on Scientific Exhibit Awards, composed of Drs. Walter P. Anderton, Walter G. Hayward, William A. Groat, Nelson G. Russell, and myself, is pleased to render the following report after careful study and evaluation:

SCIENTIFIC RESEARCH

First Award:
Abraham L. Kornzweig, M.D.
Mount Sinai Hospital, New York
"Embryologic Development of the Cornea, Sclera, and Corneo-Scleral Junction"

Second Award:
Udall J. Salmon, M.D.
Samuel H. Geist, M.D.
Charles S. Poole, M.D.
A. Austin Salmon, B.S.
Mount Sinai Hospital, New York
"A Two-Hour Pregnancy Test"

CLINICAL RESEARCH

First Award:
S. A. Goldberg, M.D., Newark, New Jersey
S. N. Blackberg, M.D., Chicago
Phyllis Stanley, M.T., Newark, New Jersey
"The Pathology of Arthritis"

Second Award:
Henry K. Taylor, M.D.
Goldwater Memorial Hospital, New York
"Bone Infarcts and Aseptic Necrosis"

Honorable Mention:
Lee A. Hadley, M.D.
Syracuse University, Syracuse
"Cervical Spine Studies"

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. *The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.*

Tuberculosis and Diseases of the Chest

A TEACHING Day on "Tuberculosis and Diseases of the Chest" has been arranged for Friday, July 9, at the Onondaga Sanatorium in Syracuse. The meeting will be opened by Charles D. Post, M.D., chairman of the subcommittee on tuberculosis and diseases of the chest of the Medical Society of the State of New York. The day's schedule is as follows:

3:00 P.M. Opening remarks by Edward S. Godfrey, Jr., M.D., Commissioner of Health, New York State Department of Health.
"Pulmonary Tuberculosis: Early Diagnosis and Differential Diagnosis," by Reuben J. Erickson, M.D., associate professor of medicine, Albany Medical College, and director, Tuberculosis Service, Albany Hospital, with discussion by Herbert C. Yeckel, M.D., president, Onondaga County Medical Society, and George C. Goewey, M.D., secretary, Syracuse Academy of Medicine.
"Bronchoscopy as a Diagnostic Aid in Diseases of the Chest," by Irl H. Blaisdell, M.D., instructor in clinical otolaryngology, Syracuse University College of Medicine.
"Common Thoracic Emergencies," by Ethan Flagg Butler, M.D., principal thoracic surgeon, Hermann M. Biggs Memorial Hospital, Ithaca.

6:00 P.M. Dinner at the Onondaga Sanatorium.
8:00 P.M. "Surgical Treatment of Pulmonary Tuberculosis," by J. Maxwell Chamberlain, M.D., principal thoracic surgeon, Homer Folks Tuberculosis Hospital, Oneonta, and Edward Sawtelle Welles, M.D., surgeon, Saranac Laboratory, Saranac Lake.
"Surgical Treatment of Nontuberculous Lung Conditions," by Ethan Flagg Butler, M.D., and Albert G. Swift, professor emeritus of surgery, Syracuse University College of Medicine.

Chairman of the evening meeting will be Edward C. Reifenstein, M.D., president of the Fifth District Branch, Medical Society of the State of New York.

Reservations for the dinner must be made in advance through Eugene W. Bogardus, M.D., Onondaga Sanatorium, West Seneca Turnpike, Syracuse, New York, chairman of the local committee on arrangements.

Sponsors of the Teaching Day are Cortland, Cayuga, Herkimer, Jefferson, Lewis, Madison, Oneida, Onondaga, and Oswego County medical societies; Central New York Chest X-Ray Conference; [illegible] nty Sanatorium; Syracuse [illegible]: Syracuse University College [illegible] Department of Health; Central New York Roentgen-Ray Society; New York State Department of Health; and the Medical Society of the State of New York.

Symposium on Wartime Nutrition

STUDYING wartime nutrition, physicians and dentists gathered at the Hotel Statler, Buffalo, on June 24, for a symposium on the principles of diet. The meeting opened at 2:30 P.M., with Harold F. R. Brown, M.D., president of the Medical Society of Erie County, presiding. The program included:

2:30 P.M. "The Normal Diet (The Intelligent Use of the Ration Ticket)," by Edgar C. Beck, M.D., assistant professor of medicine, University of Buffalo School of Medicine.
"The Basic Principles of Diet in the T[illegible] of Disease," Donovan J. [illegible]ociate professor of [illegible]. University College [illegible]l Surgeons.
[illegible]e of Vitamins in Therapy," by Fred L. Adair, M.D., Civilian Food Requirements Branch, Food Distribution Administration, United States Department of Agriculture.

7:00 P.M. Dinner meeting, Hotel Statler Ballroom.
Greetings were given by William J. Orr, M.D., president of the Alumni Association of the School of Medicine, University of Buffalo; Ernest A. McMinn, D.D.S., [illegible] District D[illegible] York; and Mrs. Harold B. Johnson, president of the Woman's Auxiliary of the Medical Society of the County of Erie.
"Food and the Future," by W. W. Bauer, M.D., director of the Bureau of Health Education, American Medical Association.

The symposium was presented under the auspices of the Alumni Association of the School of Medicine, University of Buffalo; the Buffalo Academy of Medicine; the Buffalo Dental Association; the Buffalo War Council Nutritional Committee; the Eighth District Branch of the [illegible]y of the State of New York; the [illegible]tal Society of the State of New [illegible] Society of the County of Erie; the New York State Department of Health; and the Woman's Auxiliary of the Medical Society of the County of Erie.

All those in favor will please rise.

....The delegates arose and applauded.....

Section 102

Vote of Thanks to the Speaker

DR. LEO F. SIMPSON, *Monroe:* I wish to move, Mr. Speaker, that this House of Delegates by a rising vote express its appreciation for the masterful way in which our Speaker, Dr. Bauer, has conducted this meeting.

....The delegates arose and applauded.....

SPEAKER BAUER: I thank you very much.

Dr. Wertz has asked me to announce that the Civilian Defense Dinner tonight will take place in the Ballroom at 7:00 P.M. He has asked you to be prompt because some of the speakers have to leave early to make trains.

If there is no further business to come before this House of Delegates, all reference committees having reported, I declare the 137th Session of the House of Delegates of the Medical Society of the State of New York adjourned sine die.

(The session adjourned at 2:25 P.M.)

EFFECTS OF WAR DISCUSSED AT NEUROLOGIC MEETING

According to Dr. Foster Kennedy, of Cornell University and Bellevue Hospital, more neuroses are caused by petty annoyances than by bombings from planes. Dr. Kennedy dis ussed the effects of bombings on civilians in his talk before the sixty-ninth annual meeting of the American Neurological Association, which was held recently in New York City.

Reports from England and Spain, he said, indicate that the civilian population gives little trouble under bombing but that shelling produces more serious effects. Petty annoyances of a disturbed life, such as lack of sleep and altered plans, are more often the cause of neuroses.

Another speaker at the meeting predicted that new te[illegible] war, would be added to the [illegible]. Commander Francis J. Bra[illegible], U.S.N.R., named as examples of the new terms, "convoy jitters" and "submarine nerves." Commander Braceland also said that psychiatry plays an important part in Army and Navy medicine. Special problems are being presented now with the induction of the 17- and 18-year-old groups.

Other announcements made before the Association included one by Dr. Paul Weiss, of Chicago, who explained his system of storing fragments of nerves for future use as grafts. They are frozen at −150 C., dehydrated in a vacuum, sealed in, and stored in a dry condition.

TUBERCULOSIS AMONG THE ELDERLY

One of the greatest deficiencies in tuberculosis control programs has been the failure to make sufficient use of case-finding technics in discovering the elderly person with undiagnosed pulmonary tuberculosis.

There is much evidence that the older individual suffering from this disease frequently escapes recognition and may act as a spreader of tuberculosis in the community for many years. Elderly tuberculous persons whose disease has become more or less stabilized may be robust, well nourished, and present an appearance of complete health. Many have only minor symptoms and frequently are able to work and to carry on a normal life. They often live out their natural life span, dying, not of tuberculosis, but of some entirely unrelated disease.—R. E. Miller and Beatrice Henderson: *American Review of Tuberculosis.*

"The Wisest X-Ray Investment We Ever Made"

That's how hundreds of x-ray laboratories feel about G-E's *Periodical Inspection and Adjustment Service,* which keeps their equipment in A-1 operating condition the year round.

Just as your automobile continues to give the most satisfactory and most economical performance, year after year, when competently serviced at regular intervals, so it is with fine x-ray equipment. To this end *P. I. and A. Service* has for thirteen years been extended to x-ray users everywhere through G-E's nationwide field organization. And continues despite difficulties imposed by today's wartime restrictions.

P. I. and A. is a tangible service. The owner of x-ray equipment actually contracts for it, stipulating the number of periodical equipment check-ups he desires the G-E Service Engineer to make during the year. And you'll find upon inquiring among those who have long used this service, that they consider it a negligibly low-cost insurance on their original investment. Yes, needed minor adjustments, when immediately attended to, help to prevent serious trouble and costly repairs.

In your vicinity, this service is extended through the G-E offices and regional service depots listed herewith. You can rely on our factory-trained men in these offices to give you helpful technical information at all times.

Woman's Auxiliary

To the Medical Society of the State of New York

Convention News

THE annual convention of the Woman's Auxiliary to the Medical Society of the State of New York was held at the Hotel Statler, May 2 to 5. One hundred and fifty-two doctors' wives were registered, and 32 Executive Board members and 17 county presidents took time out of their busy lives to attend the meetings. The Erie County Auxiliary gave everyone a hearty welcome and a good time.

After Mrs. J. Emerson Noll, State President, opened the meeting Monday morning, the invocation was given by Dr. Albert G. Butzer, of the Westminster Presbyterian Church, Buffalo. This was followed by a pledge of allegiance to the American flag. Responding to a tribute to the Auxiliary and a welcome to Buffalo, Mrs. John B. Horner thanked Erie County members for the program.

Dr. George W. Cottis, President of the State Medical Society, addressed the meeting. He spoke of the amazing attendance of the doctors, which, he said, represented the influence of their wives. He reminded us that women will have greater and greater importance in politics. We must swing the votes and use our influence along the proper channels, he said.

Mrs. Luther H. Kice, past State President, placed white roses in a vase for the departed Auxiliary members and for members of the armed forces who have given their lives. Mrs. Kice recited "In Flanders' Fields"—a torch for us to carry on.

The list of the departed Auxiliary members includes:

Mrs. Willian Hodge, Niagara County; Mrs. Richard P. Doody, Rensselaer County; Mrs. Dudley Kathan and Mrs. Kent Clark, Schenectady County; Mrs. Charles L. Borzelleri, Sr., Mrs. John Elliott, Mrs. Charles Irish, and Mrs. John F. Glasser, Erie County.

Mrs. J. Emerson Noll, President, gave a complete report of the year's work. Mrs. F. Leslie Sullivan, President-Elect, addressed the meeting, asking for the same cooperation which has been given to the presidents in the past. Very gratifying reports were given by the chairmen of committees and by the county presidents. This year the usual aid, gifts, and remembrances have been furnished the Physicians' Home. This is to be continued. Mrs. G. Scott Towne reported 67 subscriptions to the *National Bulletin*.

At the Annual Dinner Monday night musical selections were given by Miss Audrey Ely, soloist, accompanied by Arthur J. Crosson. Rabbi Joseph L. Fink was the guest speaker. "What kind of Victory will we want?" he asked. "We must rise above hatred and make peace secure in our world." He used the words of Patrick Henry—"Give me liberty or give me death."

On Tuesday the State Medical Society entertained the Auxiliary at a luncheon. Dr. Daniel E. Stedem, of Kenmore, and Dr. Nathan Van Etten, of New York City, were the speakers. Mrs. A. Lawton Bennett was the luncheon chairman; Mrs. Noll was toastmistress.

Seated at the speaker's table were: Mrs. F. Leslie Sullivan, President-Elect, Mrs. Louis A. Van Kleeck, Mrs. William Lavelle, Mrs. Luther H. Kice, Mrs. Carlton F. Potter, Mrs. Carlton E. Wertz, and Mrs. Harold B. Johnson, President of the Woman's Auxiliary to Erie County. Mrs. Johnson presented a beautiful silver tray to Mrs. Noll on behalf of the Executive Board, and orchids were presented to Mrs. Sullivan by Schenectady County.

The entertainment was "Flower Arrangement" by Mr. Thomas Arrigo, of the Hotel Statler Flower Shop.

On Wednesday Mrs. F. Leslie Sullivan, our new President, opened the postconvention meeting. The State Auxiliary presented Mrs. Sullivan with gardenias, and Erie County presented her with roses.

The postconvention meeting was followed by a round-table discussion led by Mrs. W. W. Street.

The Erie County members were hostesses at a tea Wednesday afternoon in the Iroquois Room. All visiting doctors' wives and auxiliary members were their guests.

The gratitude of the Auxiliary members must be expressed again to Erie County for a royal reception and a grand time. We extend our appreciation to Mrs. J. Emerson Noll, the retiring President, and our best wishes to Mrs. J. Leslie Sullivan, our new President. Let us renew our pledge and give Mrs. Sullivan the same wholehearted cooperation that has been shown in the past.

MORE HOSPITAL BEDS...MORE FIGHTING MEN

—the promise of 'Sulfasuxidine' succinylsulfathiazole

• 'Sulfasuxidine' succinylsulfathiazole, Sharp & Dohme's new, clinically nontoxic intestinal bacteriostat, shortens hospitalization[1] by contributing to uncomplicated convalescence after abdominal surgery and is also effective in treatment and control of bacillary dysentery,[2] one of the major hazards of military life.[3]

• • •

This new compound is administered orally for three to five days prior to hospitalization in order to alter the bacterial flora of the intestinal tract and reduce the possibility of peritonitis. Post-operative administration of 'Sulfasuxidine' succinylsulfathiazole contributes to smoother, shorter convalescence.

Bacillary dysentery responds to 'Sulfasuxidine' succinylsulfathiazole promptly at all stages of the disease and carriers also appear to be favorably influenced by the drug.[4]

The remarkably low toxicity of 'Sulfasuxidine' succinylsulfathiazole is partly explained by the fact that the drug is poorly absorbed from the intestinal tract . . . less than 5% is excreted by the kidneys.

'Sulfasuxidine' succinylsulfathiazole is supplied in compressed, 0.5 Gm. tablets, in bottles of 100, 500 and 1,000. Sharp & Dohme . . . Philadelphia

BEZON

WHOLE NATURAL VITAMIN B COMPLEX

The entire potency of BEZON is obtained from natural sources. By avoidance of "spiking" with synthetic vitamin factors, BEZON offers the completeness in B Complex therapy which can be obtained only from Nature

The high potency of BEZON enables you to prescribe a convenient and palatable preparation of *Whole Natural* Vitamin B Complex, without substituting synthetic for natural components and eliminates the inconvenience of numerous tablets or spoonfuls daily.

BEZON*

—concentrated to high potency from natural sources—no synthetic vitamin factors are added. Only in the *Whole Natural* Vitamin B Complex can all 16 vitamin B factors be obtained.

BEZON is made only in the distinctive two-color gelatin capsule.

Samples and literature available on request.

"CRYPTIC NOSTALGIA" IN SERVICEMEN

In a recent issue of *War Medicine,* Lieut. Comdr. C. L. Wittson, Lieut. Comdr. H. I. Harris, and Lieut. W. A. Hunt, of the Medical Corps, U.S. Naval Reserve, describe a condition which they call "cryptic or hidden" nostalgia in servicemen. According to the authors, cryptic nostalgia differs from ordinary homesickness in that it is a home fixation that may easily be confused with simple schizophrenia.

A patient suffering from this disorder appears calm and shows no agitation. Nevertheless, he is at all times completely preoccupied with thoughts of his home and friends, and everything else is excluded from his mind.

Such a condition may result in maladjustment, for the recruit will have difficulty learning and will be generally unreliable and incompetent.

NEW USES FOR VITAMIN A

At a recent meeting of the American C Society two advances in the use of vitamin reported. One is the treatment of wl cough with the vitamin, and the other is t covery that the protein constituent enables tl to store a supply of vitamin A for emergen

Dr. August B. McCoord, of the Univer Rochester, and his coworkers, reported th deficient in vitamin A have little chance vival when inoculated with whooping coug those with sufficient amounts of the vitar cover from the disease.

Study of the essential protein factor, tryto showed that its absence was accompanied low content of vitamin A stored in the liver the livers of animals that received the sul in their diet had a high vitamin A content.

POSTWAR TUBERCULOSIS THREAT

In the February *Bulletin* of the National Tuberculosis Association, Dr. Robert Plunkett, General Superintendent of Tuberculosis Hospitals, New York State Department of Health, predicted that tuberculosis will assume the proportions of a plague in Europe as the war progresses.

For control of the disease, Dr. Plunkett outlined a threefold plan, listing these suggestions: a partnership of governmental and private agencies in developing the control program; the use of American physicians and x-ray technicians who have gained experience with the armed forces; and the foreign service of the vast amounts of x-ray ment employed in the examination of servi

Dr. Plunkett has also reported that for th time in twenty years the tuberculosis death ra shown an increase. The total gain was 113 d or a 4.7 per cent gain.

The majority of the 922 new cases discove 1942 were found through the use of x-ray, b the Selective Service program and in the s now being conducted in mental hospitals.

KE so many women in their forties, she's joined her adults of the family in the task of winning e war. She's thinking more of passengers than tea parties . . . more of switches than of sew-g. But her thoughts are also on another prob-n—of how the menopause will affect her.

Two decades ago women were inclined to fear ir forties. Today they may face them with con-ence, secure in the knowledge that adequate rogenic therapy will often relieve the distress-3 vasomotor symptoms of the menopause. omen can be kept physically and emotionally and "on the job."

Striking therapeutic results have been obtained th both natural and synthetic estrogenic sub-nces. Both Amniotin (natural estrogenic sub-nce) and Diethylstilbestrol Squibb (synthetic rogen) are available in dosage forms for oral, podermic, and intravaginal administration. ethylstilbestrol is lower in cost and, in contrast natural estrogens, is only slightly less effective lly than intramuscularly. However, its high ency necessitates cautious use and indicates advisability, in some instances, of building up the estrogenic level with Amniotin by injection and then of maintaining therapy with small oral doses of Diethylstilbestrol.

SQUIBB ESTROGENIC SUBSTANCES.

AMNIOTIN . . . A highly purified, non-crystalline preparation of naturally occurring estrogenic substances derived from pregnant equine urine. Its estrogenic activity is expressed in terms of the equivalent of international units of estrone. Available in capsules for oral administration; solution for intramuscular injection; and vaginal suppositories.

DIETHYLSTILBESTROL . . . A low cost synthetic estrogen possessing the physiologic properties of estrogenic substances derived from natural sources. Highly effective orally. Available in tablets for oral administration; solution for intramuscular injection; and vaginal suppositories.

New A.M.A. Council on Medical Care

THE House of Delegates of the American Medical Association voted at the A.M.A. meeting in Chicago to establish a council on medical service and public relations, to "streamline" medical practice in America with changing times.

Following the action of the House, the Board of Trustees of the A.M.A. appointed the new group to tackle the problems of working out a system that will make possible the provision of satisfactory medical care for all the people with the least possible interference by nonmedical agencies.

The new group consists of six members of the A.M.A. "geographically distributed over the United States," in addition to the president, the immediate past-president, the secretary, and a member of the board of trustees.

The new council includes the following physicians: Louis H. Bauer, of Hempstead, L.I.; John H. Fitzgibbon, of Portland, Ore.; Alfred W. Adson, of Rochester, Minn.; James R. McVay, of Kansas City; E. J. McCormick, of Toledo; W. S. Leathers, of Nashville; Brig. Gen. Fred H. Rankin, of Lexington, Ky., retiring president; James E. Paullin, of Atlanta, president; Olin West, of Chicago, secretary; and Roger I. Lee, of Boston, chairman of the board of trustees.

The duties of the new council were officially stated to be the following:

"To make available facts, data, and medical opinions with respect to timely and adequate rendition of medical care to the American people.

"To inform the constituent associations and component societies of proposed changes affecting medical care in the nation.

"To inform constituent associations and component societies regarding the activities of the council.

"To investigate matters pertaining to the economic, social, and similar aspects of medical care for all the people.

"To study and suggest means for the distribution of medical services to the public consistent with the principles adopted by the house of delegates.

"To develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association."

The resolution provided that for the first year six members who are not officers of the associat shall be appointed by the board of trustees. term of membership is for three years. At the of the first year, however, there will be an elect of two members for one year, two for two ye and two for three years. After the first year, board of trustees will present to the house of d gates for election to membership on this counc list of three nominees for each vacancy. The ch man will be selected by the council from its elec members.

The house of delegates also appointed an eig man committee on postwar medical service, signed to study postwar medical problems, includ the care of the civilian populations in counti occupied by American troops.

It was pointed out that the civilian populat of such countries must receive medical care to p tect the American troops that will live in th midst.

The committee is headed by Dr. Roger I. Lee, Boston. Other members are Brig. Gen. Rank Francis Blake, of New Haven, Connecticut; J Paullin; Harrison H. Shoulders, of Nashvil Alan Gregg, medical director of the Rockefel Foundation, New York; Captain William Agne U.S. Navy, Washington; and Warren F. Drap Assistant Surgeon General, Public Health Servi Washington.

Dr. Herman L. Kretschmer, Chicago urologi who served for many years as treasurer of t A.M.A., became president-elect of the associati at the annual election held by the delegates. will assume office as president in 1944.

Other officers elected were Dr. John J. Ames pediatrician, of Denver, vice-president; Dr. Josi J. Moore, Chicago pathologist, treasurer. West was re-elected secretary, Dr. Shoulders w re-elected speaker of the house, and Dr. R. Fouts, of Omaha, was re-elected vice-speaker. Ernest E. Irons, of Chicago, and Dr. William Braasch were re-elected members of the board trustees.

The delegates selected New York for their 19 convention, providing that the war is ended by th time. St. Louis was selected for the convention 1945, and San Francisco for 1946.

Kirk Is Surgeon General of Army

ON JUNE 1 Major Gen. Norman T. Kirk became Surgeon General of the Army, succeeding Major Gen. James C. Magee, who retired with an excellent record for leadership and for the maintenance of high standards in the military medical service. The medical department of the Army has grown in size and importance beyond anything ever previously anticipated. There are now 34 general hospitals and about 500 station hospitals in the continental United States and a great number of other army hospitals scattered throughout the world. Brigadier General Kirk, who as surgeon general will hold the rank of major general, relinquished at the time of his appointment the position of commanding officer of the new Percy Jones General Hospital at Battle Creek, Michigan. In 1919 General Kirk was in the surgical service Walter Reed General Hospital and later had dut at Johns Hopkins University Hospital, the Mass chusetts General Hospital, and at the Station Ho pital at Fort Sam Houston, Texas, where he becam chief of the surgical service. He served subs quently as chief of the surgical service at Sternber General Hospital in Manila, the Station Hospital Fort Mills in the Philippine Islands, again Sternberg, and later at the Walter Reed Gener Hospital in Washington. General Kirk addresse the House of Delegates of the American Medica Association at its opening session in Chicago o June 7. . . . *J.A.M.A.*

More VITAMIN B_1 · More VITAMIN B_2 · More NIACINAMIDE

The patient for whom Betaplexin is prescribed now receives a substantially greater dosage of the various factors which comprise the vitamin B complex.

The potency of the declared factors in the various forms of Betaplexin is as follows:

	ELIXIR	SYRUP	TABLETS OR CAPSULES
	Each Teaspoonful (5 cc.)	Each Teaspoonful (5 cc.)	Each Tablet or Capsule
VITAMIN B_1	3 mg. (1000 U.S.P. units)	3 mg. (1000 U.S.P. units)	1.5 mg. (500 U.S.P. units)
VITAMIN B_2	1 mg.	1 mg.	0.5 mg.
VITAMIN B_6	0.3 mg.	0.675 mg.	0.1 mg.
NIACINAMIDE	10 mg.	10 mg.	5 mg.
PANTOTHENIC ACID	0.75 mg.	1.8 mg.	0.275 mg.

All forms also contain other factors including biotin, choline, inositol and para-aminobenzoic acid.

HOW SUPPLIED

Betaplexin Elixir and Syrup: Bottles of 4 and 16 fluidounces and 1 gallon.
Betaplexin Tablets and Capsules: Bottles of 50 and 500.

County News

Clinton County

The semiannual meeting of the county society was held on May 18 at the Hotel Witherill in Plattsburgh.

A business meeting at 5:30 P.M. opened the program, followed by dinner in the fountain room at 6:30 P.M..

After dinner Dr. Paul C. Clark, of Syracuse, assistant professor of clinical medicine, Syracuse University College of Medicine, gave an address on "Blood Plasma Therapy and Whole Blood Transfusion."

The instruction was arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York and the New York State Department of Health in Cooperation with the Medical Division of the office of Civilian Defense and the Health Preparedness Commission of the State of New York.—*T. A. Rogers, Secretary*

Columbia County

The regular semiannual meeting of the county society was held at the Columbia Country Club on May 11.*

Dutchess County

Dr. J. Spottiswood Taylor, director of laboratories, of Kingston, was the speaker at a meeting of the county society at the golfhouse at the Hudson River State Hospital on May 12. His topic was, "Blood and Plasma Bank in Smaller Medical Centers." A film on blood plasma was another feature of the program. Blood donors in Kingston have rallied in large numbers to meet the needs for reserve supplies of both whole blood and blood plasma, it was said. Blood banks developed in Kingston were reported to be sufficient to supply the needs of Ulster County.

Essex County

The Essex County Medical Society held its semiannual meeting at the Deer's Head Inn in Elizabethtown on Tuesday, June 1. The speaker was Dr. James Lade, of Albany, director of the Division of Syphilis Control, whose subject was "The Newer Methods of Treatment of Syphilis."*

Franklin County

Dr. Fred H. C. Heise, medical director of Trudeau Sanatorium, was named president-elect of the National Tuberculosis Association, which held its annual meeting in St. Louis, Missouri, in May.

Dr. Heise will assume his duties as president of the association next year.*

Fulton County

Dr. J. Edward Grant, of Northville, was reelected president of the Fulton County Tuberculosis and Public Health Association at the annual meeting held on May 26. Dr. William Siegal, director of the Department of Tuberculosis of the New York State Department of Health, was guest speaker. Dr. Grant presided at the luncheon session which was attended by 40 representatives of various local and state health agencies.*

Genesee County

Transferred from Portland, Oregon, to the Veterans' Facility in Batavia, Dr. Morris Dressler has arrived to assume his duties as a medical officer on the staff of the hospital. Dr. Dressler is replacing Dr. Abraham Falk, who enlisted in the Army.*

Herkimer County

The June meeting of the county society was held at 4:00 P.M. on June 8 at the Herkimer County Historical Building. Dr. V. M. Parkinson, superintendent of Pine Crest Sanatorium, presented several case reports on diseases of the chest.*

Jefferson County

The regular monthly meeting of the county society took place on Thursday, June 17, at the Jefferson County Golf Club. The speaker was Dr. Floyd Winslow, of Rochester, former president of the New York State Medical Society.*

Monroe County

Five physicians were honored by the Rochester Academy of Medicine at its annual meeting in May.

The following awards were made: The Albert David Kaiser Medal to Dr. Arthur M. Johnson, city health officer; the Dr. John W. MacCauley prize to Dr. Arthur R. Hartwig, of Genesee Hospital; the Taylor Instrument Company's prize jointly to Dr. Robert L. Sewell, of Strong Memorial Hospital and Dr. Andrew Kerr Jr., of General Hospital, and the Paine Drug Company's award to Dr. Gerard del Junco.

At the meeting winning papers were read and two plaques unveiled and presented to the Academy. The first, given by Dr. George H. Gage and Dr. Arthur P. Reed, bears the name of every doctor in Monroe County who served in World War I; the second, presented by Dr. Clarence P. Thomas, lists Monroe County physicians serving in the present conflict.*

New York County

On June 8, Dr. Hiram N. Vineberg, consulting gynecologist to the Mount Sinai Hospital, was presented with a testimonial volume of original scientific writings, honoring his sixty-five years of service in medicine, in a ceremony at the hospital's Blumenthal Auditorium. Speakers at the presentation ceremony included Hon. Leo Arnstein, Dr. Bernard Sachs, Dr. George Gray Ward, Margaret Sanger, Hon. Douglas S. Cole, Arthur Hays Sulzberger, Dr. Harold Neuhof, and Dr. Isidor C. Rubin.

Odd Facts About Tired Feelings

"A peanut gives enough energy for two hours of mental work.

"Muscles tire even if one is resting or sleeping in a noisy place, and make one get up tired.

"A person may worry himself tired, but the nerves do not know it—they keep on working. Nervous fatigue may be just plain self-pity.

"Coffee will help that tired feeling.

"Morning tiredness is rarely due to genuine fatigue. It is more likely due to the fact that one dislikes one's job and is reluctant to go to work.

"Women's blood has fewer red cells to carry fatigue-offsetting oxygen.

"Some people are born tired. A person who has a small trunk, soft flesh, and sloping shoulders has the asthenic, or quickly tired constitution.

"An oxygen debt, or lack, is a very real cause of fatigue in arms, legs.

"Tests have shown that people who do strenuous or monotonous work tire less when they eat five smallish meals a day.

"There is no wrong side for sleeping.

"About every tenth person is more tired than he should be because he should wear glasses.

"It is more restful if one stretches one's legs out, rather than cross them."—*Dr. Donald A. Laird, Saturday Home Magazine*

OCD Gives Rules for Hospital Units

ONE hundred ninety-one hospitals and medical schools have been invited by the Surgeon General of the U.S. Public Health Service to organize affiliated hospital units of the Emergency Medical Service to the U.S. Office of Civilian Defense. The invitation was extended to so large a number of civilian hospitals because each unit will be called upon for service only in a war emergency affecting its own region. Units will be activated only in event of a grave military disaster affecting the civilian population or military personnel in the area in which the parent hospital is located. Activation of a unit will take place only upon recommendation of the State Chief of Emergency Medical Service and the Office of Civilian Defense Regional Medical Officer, subject to certain limitations imposed by the Surgeon General and the Chief Medical Officer of the Office of Civilian Defense and by agreements with the invited hospitals.

Because these limitations may not as yet be understood by all physicians and hospitals which have been invited to participate in the Emergency Medical Service, the rules governing activation of affiliated units are set down as follows:

1. Members of the staffs of affiliated units are commissioned in the inactive reserve of the U.S. Public Health Service, generally with the rank of Passed Assistant Surgeon, Surgeon, or Senior Surgeon (equivalent, respectively, to Army ranks of Captain, Major, or Lieutenant Colonel). They will remain on inactive status for the duration of the war unless urgent need for their services should arise in their region because of an air raid or other grave wartime disaster. When activated under such circumstances, these officers will receive the pay and allowances of officers of equivalent grades in the armed forces.

2. The two specific purposes for which a unit may be activated are:

(a) For duty in an Emergency Base Hospital to which civilian casualties and other hospitalized patients must be transferred because a community is under enemy attack and one or more of its hospitals must be evacuated.

(b) For temporary duty to assist the armed forces at the time of an extraordinary military emergency which may temporarily overtax local military hospital facilities. Such temporary assistance will be provided in or near the locality in which an affiliated unit has been organized. The period of emergency assistance is expected to be of short duration and will last only until the Surgeon General of the Army can send in additional medical officers or until he can distribute the excessive load of sick and wounded to military hospitals in other parts of the country. Affiliated units are organized primarily for civilian protection and are not to be used to staff military hospitals as they expand to meet increasing medical requirements of the Army.

3. Since affiliated units are organized by the Medical Division of the Office of Civilian Defense as part of the Emergency Medical Service of their states, they will be expected to provide aid only in their own or neighboring states. Their members will not be detached for duty in other parts of the country nor, in accordance with the terms of their recruitment, will they be activated for any other duty except those listed in paragraph 2 of this statement.

4. A unit organized from the staff of a teaching hospital of a medical school will not be called unless the hospital itself must be evacuated or unless there is no unit from a nonteaching hospital to meet the emergency need.

5. The period of obligation for service will cease at the termination of the present national emergency; the Surgeon General will accept resignations of members of units 6 months after cessation of hostilities.

6. A commission in the inactive reserve of the U.S. Public Health Service does not prevent a member of an affiliated unit from entering the armed forces; resignation will be accepted for this purpose.

7. Members of affiliated units may wear the authorized lapel buttons which indicate that they have enlisted for emergency service. They are not to wear the uniform until called to active service and need not purchase a uniform unless the possibility of active service is imminent. Uniforms will not be required for brief periods of active service.

Because it is essential for civilian protection, the organization of affiliated units has received approval of the Board of Trustees of the American Medical Association. For the same reason, the Directing Board of the Procurement and Assignment Service has authorized "essential" physicians to accept positions in affiliated units.

At the Helm

Dr. A. A. Savastano, of Haverstraw, has been appointed to the staff of the Hospital for Ruptured and Crippled in New York City. He is already a staff member of the Polyclinic Hospital in New York City and the Long Island College Hospital in Brooklyn.*

• • •

Mrs. Letta Button, of New Berlin, has been named to the board of visitors of the Binghamton State Hospital by Governor Thomas E. Dewey for a term of seven years.

Mrs. Button will succeed Leo R. Harrison, of Greene, whose term expired on December 31, 1942.

Governor Dewey also appointed Dr. J. Mott Crumb, of South Otselic, to the board of visitors to the Women's Relief Corps Home at Oxford. He will succeed Herbert N. Griffin, Oxford postmaster, whose term of office expired in February. Dr. Crumb's term of office also is for seven years.

Dr. Crumb has practiced medicine since 1903. He is a member of the associate staff at the Chenango Memorial Hospital.*

Sterilizing Air

Triethylene glycol vapor, which is not toxic to human beings, can be used with complete safety to kill air-borne bacteria, according to Dr Oswald H. Robertson He had previously discovered that one part glycol to 200,000,000 parts of air will destroy the germs and viruses of pneumonia, streptococcus infection, influenza, and probably the common cold, in auditoriums and theatres

Sea Vitamins

A new concentrated vitamin D-3 product made from sea mussels, mollusks and other spineless marine animals has been placed on the market in Sweden It is intended chiefly as a substitute for fish-liver oil and other now unobtainable vitamin products to fortify poultry and animal foods.

WEST HILL

[Continued from page 1270]

Dr. J. Wilson Poucher, president of the board of the Hudson River State Hospital in Poughkeepsie, was reappointed to the Board of Visitors today by Governor Thomas E. Dewey. Dr. Poucher has been a member of the hospital board since 1917.

Now in his eighty-fourth year, Dr. Poucher retired from active practice of medicine and surgery in 1928.*

• • •

Major Elizabeth L. Raynor, director of the American Women's Hospitals Reserve Corps, has announced the appointment of Lieutenant Alice M. Donohue, head of the North Shore division of the Corps. Lieutenant Donohue is former national president of the Veterans of Foreign Wars Auxiliary and has been executive secretary of the Corps for the past year.

Improvements

Prospects for an early opening of the much-needed and long-awaited Tuberculosis Pavilion of Riverside Hospital on North Brother Island appeared brighter with the announcement by the Bronx Board of Trade that it has been advised by the New York City Department of Public Works that needed equipment for the structure will soon be available.

The structure will provide approximately 150 additional beds in the borough for the care and treatment of tuberculosis victims, which represents about one-third of the 500 beds deemed necessary by the two Board committees to adequately care for tuberculosis patients in this area.

Late last year the Board of Estimate provided additional funds needed for the building by authorizing an issue of $120,000 in serial bonds and tax notes, and an additional $120,000 for furnishings and equipment.

The building has cost well over $1,000,000 to date. It is T-shaped, three stories high, with a basement and a penthouse on the roof. It will have accommodations for 152 patients and among the medical services available will be surgery, medicine, physiotherapy, eye, ear, nose, and throat surgery, dental operations, radiography, fluoroscopy, thoracic and pneumothorax operations.*

• • •

Additional hospital facilities for Harlem and appointment of colored persons to hospital staff positions were discussed at a recent conference between Dr. Edward Bernecker, Commissioner of Hospitals, and the city-wide Citizens' Committee on Harlem.

A tumor clinic and a mental hygiene clinic are being planned for Harlem Hospital, Dr. Bernecker told the committee.

Three colored doctors recently have been placed on the staffs of city institutions, a colored nurse has been promoted to supervisor, and two colored student nurses are listed for September appointments, the group was told.*

• • •

The New Rochelle League for Service has given a total of $15,000 to New Rochelle Hospital since the first of the year. This is the largest sum contributed by the League in a single year and tops last year's record donation by $1,000. The gift represents proceeds of the Xavier Cugat concert, the spring fashion show and moving picture, the Hospitality Corner, Thrift Shop, and "Bulletin."

It has been estimated that the League has donated a total of $100,604 to the hospital since 1930, $40,000 of this sum having been given in the past three years.*

Newsy Notes

Wearing the new khaki Army Nurse Corps uniform for the first time, Lieut. Col. Florence A. Blanchfield, acting superintendent, took oath as colonel and as superintendent in a brief ceremony in the office of the Army Surgeon General on June 1. Colonel Blanchfield, eighth superintendent of the 42-year-old corps, succeeds Colonel Julia O. Flikke, who has retired.*

• • •

Six Episcopal theological seminary students entered Bellevue Hospital on June 16 for a twelve weeks' course in behavior problems, under joint arrangement with the hospital and the New York Protestant Episcopal City Mission Society. The courses include lectures by hospital staff members and are directed in connection with the society's chaplaincy service.

The young men will go through the routine of being admitted as patients in order to understand hospitalization from the patients' point of view. They will don white coats with identifying purple arm bands as "theological interns" and take part in daily hospital routine also.

• • •

A Chinese Blood Bank was opened at 154 Nassau Street in New York City on June 7. It is under the auspices of the American Bureau for Medical Aid to China, whose president is Dr. Donald D. van Slyke. The blood donations will be converted into plasma and shipped to Chinese hospitals.

Dr. J. Heng Liu, medical adviser to the Chinese Division of the Lend-Lease Administration, was the first donor. Miss Betty Eng, a member of the bank staff, was the first to donate a pint of blood. Dr. John Scudder, creator of the blood bank here for Great Britain, said that the Chinese bank would accept blood from persons who had had malaria because a blood plasma sterilizer would be used.*

• • •

In its ninetieth annual report issued June 13, Mount Sinai Hospital said that although 558 of its physicians and other staff members were in the armed forces, the hospital was able to maintain its services to the community last year and treated 16,592 bed patients and 25,804 in its clinics.*

• • •

Harlem Hospital will have a new tumor clinic and mental hygiene clinic, according to an announcement by Hospitals Commissioner Edward M. Bernecker on May 25. The mental hygiene clinic will be in the new outpatient building scheduled for completion within three months.

THE MAPLES INC., OCEANSIDE, L.I.

A sanitarium especially for invalids, convalescents, chronic patients, post-operative, special diets, and body building. Six acres of landscaped lawns. Five buildings (two devoted exclusively to private rooms). Resident Physician. Rates $18 to $45 Weekly

REVIEWED

Textbook of Clinical Neurology. By Israel S. Wechsler, M.D. Fifth edition. Octavo of 840 pages, illustrated. Philadelphia, W. B. Saunders Company, 1943. Cloth, $7.50.

This is a revision of an outstanding and deservedly popular book. It has been enriched by the inclusion of the results of the advances made and the increase in knowledge during the past four years. The chemotherapy of meningitis is concisely and effectively presented. The various types of headache are thoroughly covered and indexed, including the diagnosis and treatment of the histamine variety.

The basic value of the book lies in the author's digest of his years of clinical experience and teaching in neurology. Although 40 pages are devoted to an introduction to the history of neurology, few will find any cause for complaint in view of the very interesting and critically evaluated contents.

The book is well printed, easy to read, and continues to be an authoritative guide.

LAURENT FEINIER

Adventure in Blood Transfusion. By Bertram M. Bernheim, M.D. Octavo of 182 pages, illustrated. New York, Smith & Durrell, Inc., 1942. Cloth, $2.50.

This fascinating presentation should be read by physician and layman alike. It is written by a man who has made history in the field of blood transfusion. It takes us back to way back, when the procedure was in truth an adventure; where each transfusion took more out of the transfusionist in the way of coronary metabolism than it actually gave to the patient in measured cubic centimeters and its implications.

The author is now in a position to reminisce, because he has reached the heights, and can afford, from this vantage point, to see the humor of quondam tragic situations. He takes us from the early days of direct artery-to-vein transfusion by a "new transfusion tube" and carries us through the citrate era—all these without benefit of blood typing. What a joke, if a joke it were.

And all this time the four blood groups had been discovered. However, an American was the mechanic, a European, the theorist, and neither was good without the other. This was internationalism in medicine at its lowest ebb, and so medicine, in general, and humanity, in particular, suffered.

Read it to enjoy the story of a pioneer and his transfusion trials and tribulations.

MAURICE MORRISON

Mental Illness: A Guide for the Family. By Edith M. Stern. Octavo of 134 pages. New York, The Commonwealth Fund, 1942. Cloth, $1.00.

There is much ignorance about mental illness and about its modern medical treatment. When it strikes home there is unnecessary suffering both for patients and relatives because of lack of information regarding this illness.

This book is written as a guide to the relatives of the patients as well as to the patients themselves. It discusses various topics dealing with the attitude toward mental illness, the question of hospitalization of the patient, the problem of visiting hours, the question of recovery of the patient, aftercare, and other similar subjects.

It is a valuable book that should receive a warm welcome from all intelligent people.

MEDICINE IN THE NEWS

Vitamins and Hereditary Defects

"Drs. C. C. Gordon and J. H. Sang of Aberdeen University announce that nicotinic acid, the anti-pellagra vitamin, can correct hereditary defects. Presumably with the aid of X-Rays, they developed a race of fruit flies without antennae or feelers, that is, a race which invariably passed its defect on to its progeny. Larvae of these flies fed with amounts of nicotinic acid brought forth normal insects. In the next generation and thereafter the defect again appeared. Overdoses of nicotinic acid always restored the antennae."—*Waldemar Kaempffert, N. Y. Times.*

IN WHOOPING COUGH

ELIXIR BROMAURATE IS A UNIQUE REMEDY OF UNIQUE MERIT

Cuts short the period of the illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 or 4 hours.

PHARMACEUTICAL MEDAL AWARDED TO LILLY

Joseph K. Lilly, chairman of the board of Eli Lilly & Co., was recently honored at a dinner meeting by the New York branch of the American Pharmaceutical Association "for his many accomplishments in the interests of pharmacy."

Mr. Lilly received the Remington Honor Medal for 1942, the highest honor in pharmacy, awarded each year by a committee consisting of all living past-presidents of the American Pharmaceutical Association. The award is named in memory of Professor Joseph P. Remington, of the Philadelphia College of Pharmacy and Science, one of the pioneers in modern American pharmacy. Mr. Lilly was a student of Professor Remington, having been graduated from the Philadelphia college in 1882. Mr Lilly is the twenty-sixth in the list of distinguished recipients of the medal.

• The evolution of contraceptive products is an interesting chapter in the history of medical achievement and scientific progress. A little over a decade ago, there were few authoritative requirements for these preparations. Today, physicians prescribe Ortho-Gynol with complete confidence.

It is the result of years of exhaustive research and meticulously controlled laboratory and clinical projects. Its properties share the same high degree of uniformity required by all acceptable medical preparations. The reliability of Ortho-Gynol has been attested by thousands of case histories.

Strict adherence to ethical principles through the years has made Ortho-Gynol the mo widely prescribed preparation of its kind.

IN HYPERTENSION BLOOD PRESSURE GOES DOWN

Reduction of 70-80 mm. of hg. recorded with DIURBITAL

EFFECTIVELY, GRADUALLY, SUSTAINEDLY

STRESS ON HEART EASED WITH

DIURBITAL

DIURBITAL* exerts *vasodilating, relaxing* effects on the blood vessels in hypertension. It eases the fluid burden on the heart and helps check possible cerebral or peripheral edema by *active diuresis* . . . and serves to dilate coronary arteries for *myocardial stimulation.* Relief from headache, vertigo, fear, irritability, insomnia, etc. occurs as blood pressure gradually descends. Enteric coating of DIURBITAL avoids gastric insult. DIURBITAL TABLETS CONTAIN EACH: Theobromine Sodium Salicylate 3 grs.; Phenobarbital ¼ gr.; Calcium Lactate 1½ grs. Bottles of 25 and 100 tablets at your pharmacy.

Write "DIURBITAL" on Rx blank for samples and literature.

ONLY *ONE* HAS

velvet smoothness

A comparative examination will reveal that the dome of the "Ramses"* Diaphragm possesses a surface which is really smooth as velvet. An exclusive curing process makes it possible for us to use pure gum rubber in the "Ramses" Diaphragm dome and at the same time give it strength, long life, and resistance to petroleum-containing jellies.

The flexible, rubber-cushioned rim of the "Ramses" Diaphragm protects the patient against any possible discomfort due to spring pressure. Only the "Ramses" Diaphragm has this patented feature.

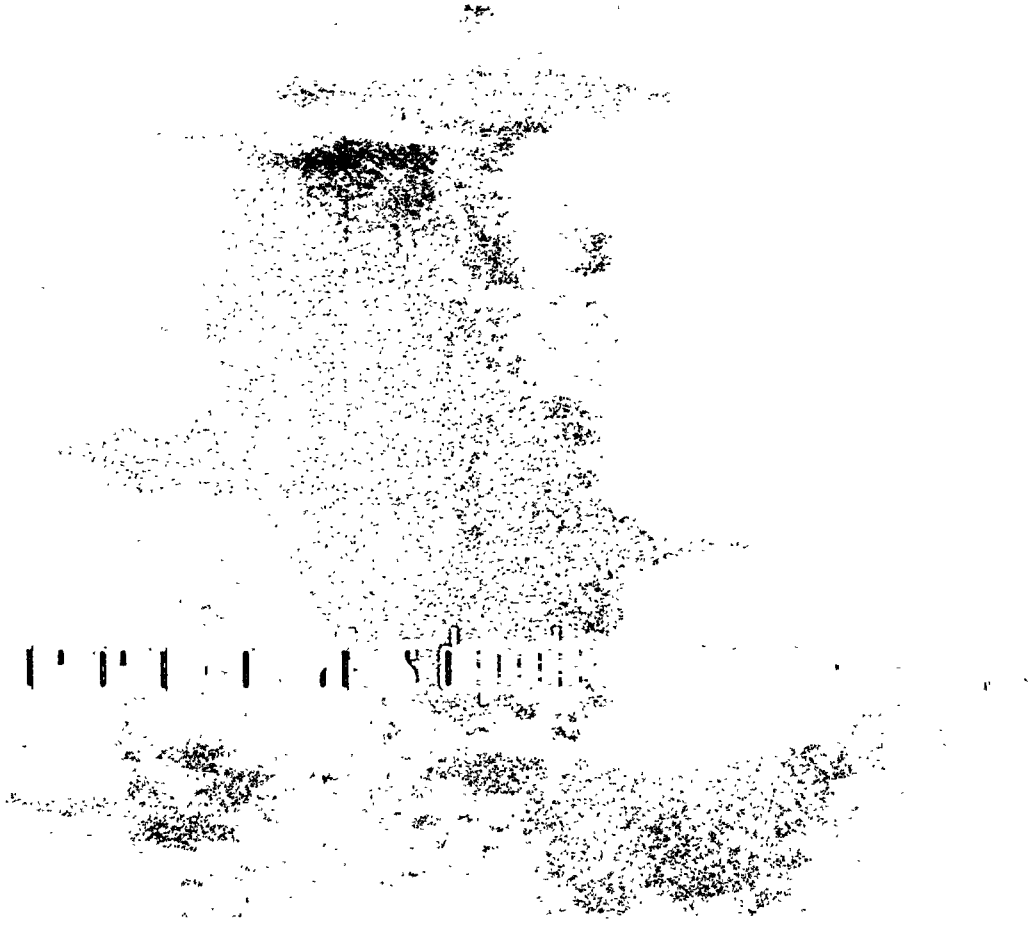
THERAPEUTIC EFFECTIVENESS
PLUS PALATABILITY



The therapeutic effectiveness of ALUMINOID, chemically non-reactive colloidal alumina has been demonstrated by ample clinical use.

Administered in capsule form, it provides the patient with convenient acceptable medication, and overcomes the objection to taste frequently exhibited against other forms of aluminum hydroxide.

Samples and literature to physicians on request.

COLLOIDAL ALUMINA
TRADE MARK

CHATHAM PHARMACEUTICALS INC. • NEWARK, N. J.

CURRENT investigators agree that a surprisingly large percentage of the population, even in upper income groups, consumes a diet inadequate in essential nutrients. Conditions prevailing today contribute to even greater, more widespread deficiencies.

The formula of White's Neo Multi-Vi Capsules is based on today's most authoritative standards of adult requirements. Each small capsule contains every major vitamin, including all those clinically proved in amounts that provide a good "safety margin" above adult basic requirements,* yet not wastefully in excess of the average patient's ability to assimilate and utilize. This is the basis of the preparation's unique economy.

WHITE'S NEO MULTI-VI CAPSULES

Each capsule contains:

Vitamin A	5,000 U.S.P. Units	Pyridoxine Hydrochloride	1 mg.
Vitamin D	500 U.S.P. Units	Calcium Pantothenate	1 mg.
Thiamine Hydrochloride, U.S.P.	1.5 mg.	Nicotinamide	20 mg.
Riboflavin	2.5 mg.	Ascorbic Acid, U.S.P.	50 mg.

Supplied in bottles of 25, 100, 500, 1000 and 5000 capsules. Ethically promoted—not advertised to the laity. White Laboratories, Inc., Newark, N. J.

*[illegible] in regulations of Food and Drug Administration, 1941

STAYING POWER

NEMESIS OF THE U-BOAT is the blimp. Whereas the value of the swift airplane in coastal patrol is restricted by its own speed, that of the blimp is enhanced by its ability to hover over its prey for long hours. The blimp has *staying power!*

This contrast also applies to local anesthetics. Nearly all exercise but a short-lived influence upon a chosen site. Eucupin is different. Its effect is not fleeting. It remains at the site of injection, causing prolonged anesthesia followed by analgesia for periods ranging from 24 hours to 5 days or more. Eucupin eliminates the hyperesthesia that usually follows transient anesthetics. *Eucupin, too, has staying power!*

Literature and samples furnished on request.

Supply: Aqueous and oil solutions for infiltration; dihydrochloride tablets for solutions for topical application; ointment and rectal suppositories; powder, base and dihydrochloride.

THESODATE *Brewer*

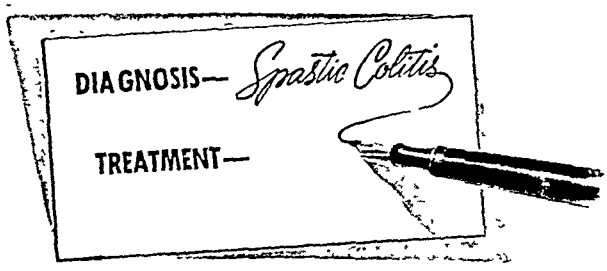
(the original enteric-coated tablet of Theobromine Sodium Acetate)

for

CLINICALLY EFFECTIVE
LOW TOXICITY
EFFECTIVELY ENTERIC COATED

CORONARY ARTERY DISEASE AND EDEMA

Medical authorities in journals and books have substantiated the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal Diseases. Actual clinical use has proven the usefulness of Thesodate *(Brewer)*.



The enteric coating of Thesodate tablets permits adequate dosage, so necessary for best results with xanthines, for as prolonged a period of time as necessary.

Supplied with or without Phenobarbital, also with Potassium Iodide and Phenobarbital, in potencies for controllable dosage.

Samples and literature on request.

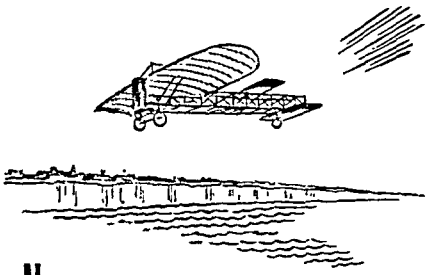
In Congestive Heart Failure

Phyllicin

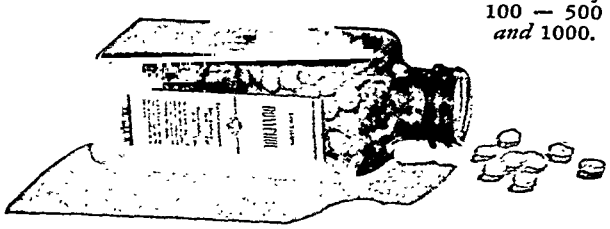


theophylline-calcium salicylate

A well tolerated, quickly acting diuretic and myocardial stimulant

DOSE: 1 tablet (4 grains) two to four times a day.

BILHUBER-KNOLL CORP. ORANGE NEW JERSEY.



Now that Fortresses and Lightnings are in the air it would be just as short-sighted to fly the channel in Bleriot's plane as it is to stay with "bile salts and cathartics" in attacking biliary stasis.

Modern, chemically pure substances of specific, predictable action for bile stimulation and bile substitution are provided in dehydrocholic and desoxycholic acids. Dehydrocholic (Triketocholanic) acid flushes the bile ducts by more than doubling the volume of fluid bile from the liver. Desoxycholic acid activates the fat-splitting enzyme in the pancreas and blood.

These major bile acids may be had in one convenient, potent preparation—It is

390,000,000 PAIRS OF SHOES . . .

but only .00000000256441 per cent of this year's rationing of shoes is of immediate interest to your foot patient with a stamp No. 18.

Britains have been saying that rationing is improving the figures of British women. Rationing of shoes here may have little effect on improving feet, unless the pinch of the rationing makes us as conscious of better shoes as it does of the limitation. It is not unlikely, however, that Americans will become more conscious of quality, durability, fitting and other features essential for comfort, support, or relief of conditions that make just "any shoe" out of question.

In which case they will hold out for better shoes . . . and if under the advice of their physician, they will expect him to prescribe a better shoe.

Now a still greater source of nutrients!

MOST of your patients, we are sure you will agree, greatly favor white bread.

And as matters stand, white bread is a greater source of important nutrients than ever before.

For today all white bread is enriched.

This foundation food now provides about four times the thiamin and twice the niacin and iron previously supplied in unenriched white bread.

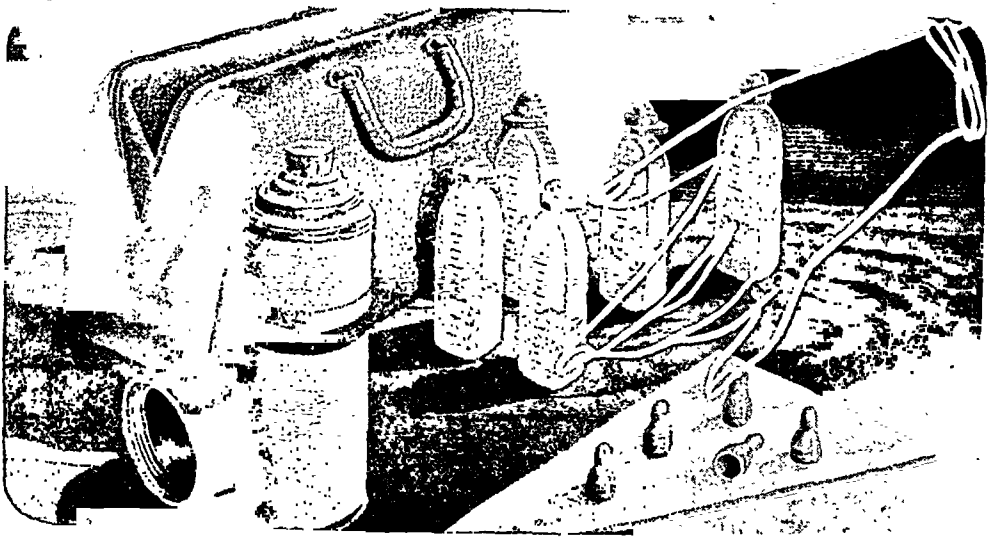
With everyone, including yourself, working under unusual pressure, demands upon energy are high. And there is great need for that energy to be replaced.

Bread helps fill this important need.

For with its abundant supply of carbohydrates and protein, bread is an excellent source of food-energy.

And enriched as it is today it becomes a particularly desirable means of increasing your patients' food-energy intake.

They enjoy it. It satisfies. And it is plentiful and inexpensive.



As it has through the ages, bread proves itself a basic food for America at war.

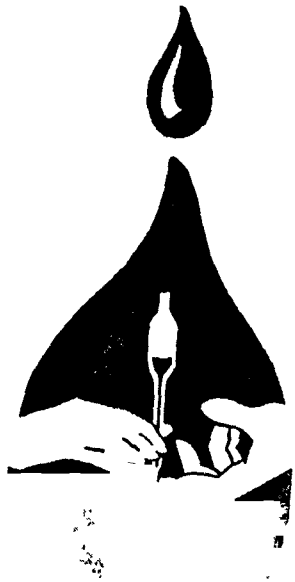
An Important Contribution to BILE ACID THERAPY

TRIKETOL is a distinct laboratory achievement representing years of original research in bile derivative chemistry. This research culminated in the production, by *proper oxidation*, of crystalline-pure, therapeutic bile acids, free from toxic, irritating contaminants inherent in crude bile. New formulations plus new equipment, of original design, contribute greatly to the exclusive ENDO method of producing TRIKETOL.

Exhibiting the two essential bile acids—dehydrocholic and dehydrodesoxycholic—at maximum therapeutic efficiency, TRIKETOL is indicated wherever an active hydrocholeretic and cholegenic is appropriate, as in chronic cholecystitis, biliary stasis and other hepatobiliary disorders.

Moreover, its ability to increase production of bile (and in subsequent secretion as thin, limpid bile) is proving highly effective in the management of constipation due to biliary stasis.



TRIKETOL

Look at the Blood!

Because of the emphatic need for iron to provide adequate hemoglobin, basic interest in the patient's hematological condition has been forcefully revived. The rationing of important iron-giving foods is being seriously considered as an underlying cause of present and potential iron deficiencies for many. Since these deficiencies present a startling resemblance to the syndrome of vitamin B complex shortages, a differentiation is sometimes difficult. And while the alert physician properly evaluates the latest trends in therapy, the time-honored axiom, 'LOOK AT THE BLOOD' is again being recognized as of paramount importance. Due to the presence of specially prepared iron (easily assimilated ferrous sulphate), hypochromic anemias are economically corrected with

AN EASILY DIGESTED PROTEIN FOOD CONCENTRATE FOR SPECIAL DIETS

Where increased protein intake is indicated, many physicians prescribe Knox Gelatine as a drink to supply concentrated pure protein in an easily digestible form. It provides special dietary supplementation in preoperative and postoperative cases, for convalescents and to assist metabolism of patients suffering from non-specific asthenia and fatigue.

Plain, unflavored Knox Gelatine is not to be confused with ready-flavored gelatine dessert powders. It is all protein and contains 7 of the 10 amino acids considered dietary essentials. In view of current shortages of meat, the high concentration of pure protein in Knox Gelatine assumes augmented significance. A pamphlet on the protein value of this gelatine is available free to the profession through use of the coupon below.

Your hospital will procure Knox Gelatine for your patients If you specify it by name.

Comparison showing equivalent quantitative protein content of Knox Gelatine and other high-protein content foods. There are qualitative differences.

Editorial

The Practical Nurse

At its annual session in 1943, the House of Delegates of the Medical Society of the State of New York recognized the seriousness of the shortage of nursing service in the State. It adopted a resolution endorsing "the movement to extend the facilities for training . . . . practical nurses and likewise commend(ing) the efforts by the Nursing Council of this State in the procurement of candidates for such training."[1]

There has long existed in the State an evident need for another type of nursing service of a less demanding character than that hitherto supplied by the highly trained professional registered nurse group. This need has been intensified during the present emergency by the lack of available nurses for maintenance of civilian hospital requirements. Somehow, these requirements will have to be met. The obvious answer seems to be extension of the present inadequate facilities for the procurement and training for this special practical nurse group.

There are at present nine schools for the training of practical nurses in the State—six in New York City, two in Albany, and one in Rochester. Students of practical nursing are not, however, trained in hospitals of the State which have established training schools for professional nursing. In addition to those trained in the nine schools, there are, according to information supplied by the Executive Secretary of the Recruitment Committee of "Practical Nurses of New York, Inc.," some 26,000 persons in the State working as practical nurses under waiver.

Formal courses in the approved schools are from nine months to a year in length, of which time 300 to 500 class hours are devoted to the regular curriculum. Instructors are registered nurses able to teach at the level between that of the volunteer worker and that of the professional nursing student. Laboratory facilities for teaching bedside nursing and home economics are provided.

Hospital affiliation provides supervised instruction and experience in the care of convalescent medical patients and also in the skills necessary for the competent care of the chronically ill patient. The practical nurse, therefore, fills the gap between the professional nurse and the volunteer worker and, when properly trained, will have received a substantial body of information in nonscientific terms on a suitable vocational level.

The movement which the House of Delegates has endorsed to extend the facilities for practical nurse training seeks to provide a larger body of prepared nurses that can be certified as competent to perform certain nursing duties in the hospital and in the home. Women from 18 to 50 can be recruited from among those having two years of high school education, from those who for one reason or another desire to leave domestic or factory work and who desire to become nurses but who cannot qualify, by reason of age or on educational or other grounds, for the longer training as registered nurses.

[1] New York State J. Med. 43: 1162 (June 15) 1943.

Extended facilities for recruiting and training such a group would unquestionably assist in reducing the cost of sickness, and aid materially in the care of the chronically ill in their homes or in convalescent homes, thereby relieving the pressures for hospital care and releasing badly needed beds. It is evident that the Nursing Council of this State and all other agencies working toward this end deserve and must get every assistance in carrying out its procurement and training program.

Industrial Health

"There are," says Leverett Bristol, M.D.,[1] chairman of the Committee on Education, Council on Industrial Health of the American Medical Association, "approximately fifty million wage earners in the United States. Among these workers it has been found that over four hundred million days are lost yearly on account of absenteeism due to sickness, with a resulting yearly cost of over three billion dollars. We must do everything possible to save this time lost from sickness as a part of our contribution to winning the war. Neither metal nor rubber, money nor manpower, but time shows the greatest shortage! Our present needs require a strengthening and broadening of the entire industrial health program all along the line, from private industry to local, state, and federal jurisdictions. As emphasized by Surgeon General Parran of the United States Public Health Service, "industrial hygiene must keep pace with the needs arising from high speed assembly lines, which will employ some fifteen million men and women within the year. Great Britain learned that it is urgently necessary to have the full-time services of a trained industrial physician in every large plant. Less than one-seventh of our workers have that service now."

Industry has been making more and more use of medical knowledge and service in recent years. Larger companies have expanded their employee health programs. Smaller companies should develop health supervision and medical services for employees, particularly those engaged in war production. Some are, in fact, doing so.[2] Plants having 500 or fewer employees comprised 60 per cent of the total of factory employment as late as 1937, and 98 per cent of the total number of manufacturing establishments of the country.[3]

These small plants must be encouraged to develop employee health programs and medical service. It is surely a function of county medical societies to promote this type of industrial service. Primarily, in conjunction with departments of health, and also with the aid and assistance of voluntary agencies. "One of the outstanding examples of postgraduate education in industrial health .... was carried out last year through brief regional institutes in nine Iowa communities, based on cooperative efforts between the state and county medical societies and the state department of health..... The purpose (of these) was to stimulate and correlate the interests in industrial medicine of general practitioners, industrial physicians, and industrial managers."[1]

Assuming that responsibility for the stimulation and teaching of the physicians who are available for this work in the county rests in the county medical society, what sort of postgraduate course should be undertaken? Bristol[1] recommends: (1) employee relations, (2) managerial relations, (3) medical relations, and (4) public health relations. Specific subjects which should be included are: common industrial health problems, including dust hazards, industrial dermatitis, and other industrial diseases of local bearing or interest; tuberculosis control; syphilis, and other nonoccupational diseases; emergency care of minor and major industrial injuries; industrial hygiene surveys with demonstrations of methods and apparatus; medicolegal aspects of

industrial health; and industrial health and the general practitioner (methods and procedures of administrations and physical examinations).

If this has been accomplished successfully elsewhere, it can be done here. Unless we create a well-informed and trained reservoir of personnel to implement the expanding programs of industry, we shall not have fulfilled our obligation completely to the war effort.

The success attained by the Long Island College of Medicine in its recent postgraduate course in industrial medicine, the educational program maintained for practitioners in Indiana, and the continuing lectures and other activities of the Council Committee on Public Health and Education have demonstrated what can be done with respect to a training program for physicians.

The more difficult task still remains of bringing this medical service into plants that have 500 or fewer employees. Undoubtedly the county medical societies can do and are doing a great deal to provide the professional service necessary, but it remains true that the great bulk of the small plants belong to no trade association, have no organization through which an educational campaign can be conducted looking to an acceptance by management of such medical services as are available in the locality on a whole or a part-time basis. The strengthening and broadening of the entire industrial health program advocated by Dr. Bristol will depend to some extent on what industry will do to set up an educational program to reach the management of the small plants. Medicine can rightly be expected to furnish competent industrial medical service and is making every effort to do so, but we are not aware of any considerable attempt on the part of industry to educate the management of the small plant to an acceptance of such medical services as are available and which organized medicine is seeking to extend by every possible means. It seems hardly within the province of medicine to undertake that job. Until industry and industrial associations undertake to stimulate interest in medical service on the part of the small plants, absenteeism and indifferent industrial health conditions will continue to prevail.

Dissolving Urinary Calculi

Dissolution of urinary calculi has long been a mirage-like therapeutic problem. Various agents, given for the purpose of altering the urine chemically in order to dissolve calculi, have yielded no beneficial results. Optimism increased when it was demonstrated that a highly acid ash diet would produce strongly acid urine, perhaps with the aid of goodly doses of ammonium chloride.

The suggestion was made that if the acidity of the urine were sufficiently great, inorganic calculi could not fail to go into solution. Such therapy in conjunction with liberal doses of vitamin A, absence of which makes an animal prone to calculus formation, raised hopes that renal calculi, if of inorganic composition, could be removed medically.[1] Calculi of organic composition, were treated with a different dietary regimen. Further studies and investigations dampened hopes for the treatment though, and all that may now be claimed for such therapy, with exceptions, is that reformation of calculi is either prevented or retarded.

A new approach to the same problem promises more definite, if limited, results. A recent revelation demonstrates that the addition of magnesium ions to a citrate solution dissolves phosphatic urinary calculi without undue irritation of the mucosa of the urinary tract.[2] Monohydrated citric acid, anhydrous magnesium oxide, and anhydrous sodium carbonate in definite proportions are dissolved in a liter of water. This solution is then injected by a retrograde cystoscopic method following a carefully devised technic so that the calculus is bathed in this solution, which has the capacity of dissolving phosphate calculi.[2] Certain preliminary precautions must be observed, notably establishment of the fact that the treated calculus is of the soluble phosphate variety. Sulfathiazole is concurrently administered to prevent or combat infection.

This new method has withstood the test of trial, brief though this trial has been. It is based upon sound chemical knowledge of calcium phosphate solubility. The solution is injected into direct and relatively prolonged contact with the

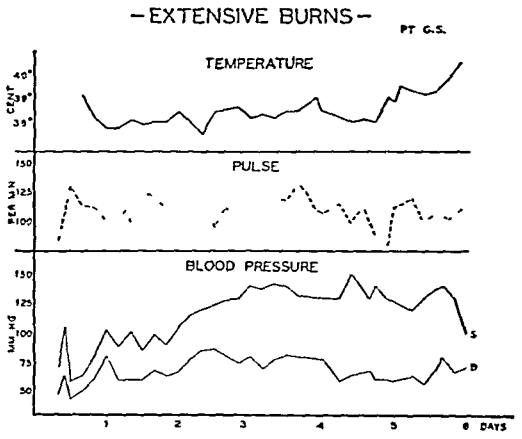

CHART 1

Wolff, and Lee[21] are more complicated, but depend on calculations derived from the hemoglobin level, hematocrit, plasma protein concentration, and body weight. These formulas are predicated on the basis that the greater part of the fluid loss occurs soon after the burn and are based on the hematocrit on admission. The burned patient may be seen before the hematocrit has increased markedly, but plasma therapy should be started at this time. Our experience indicates that it is possible to predict the concentration of plasma required at various periods of treatment, but the amount must be regulated by repeated determinations of the hematocrit and specific gravity or protein concentration of the plasma.

Case Reports

Case 1.—G. S. (R.M.H., No. 167072), admitted on December 7, 1941. The patient was a 33-year-old white man who had fallen asleep while smoking, igniting the bedclothes. The flames had been extinguished soon afterward, but on admission to the hospital he had extensive burns involving the entire trunk anteriorly and posteriorly, the buttocks, perineal region, the neck, both arms, and hands. The burns of the trunk and buttocks were almost entirely third degree except for one small area of second degree on the back. The burns on the hands were of second degree. On admission the patient was semicomatose, dyspneic, and exhibited signs of profound peripheral circulatory failure. The unburned areas were very pale and cool. Blood pressure on admission was 60/0; pulse, 120, thready and of poor quality. General physical examination aside from the burns was negative on admission. On admission the blood showed a hemoglobin of 23.5 Gm. The red blood count was 5.4 million. The white blood count was 11,750. Urine and Wassermann tests were negative.

Course in the hospital: Immediately following admission the patient's blood pressure became unobtainable; he was placed in shock position, with local heat applied to the body by means of blankets. Morphine was administered to relieve discomfort, and oxygen was given by nasal catheter. A cannula was inserted into an arm vein and intravenous plasma and saline injections were started. The amounts of plasma and saline administered are recorded in Table 1. Because of the patient's condition, which was critical, adequate débridement of the burned surfaces could not be done. After partial débridement of the wounds, the anterior burned surfaces were sprayed with tannic acid and silver nitrate. The patient could not be moved sufficiently to treat the burns of the back for about twenty-four hours, and at this time these areas were treated with sulfadiazine compresses. His condition remained very critical in spite of large amounts of saline and plasma. After thirty-six hours the blood pressure finally stabilized at 120/70, and remained within normal limits until the patient's death one month later. The temperature, pulse, and blood pressure during the first week are recorded in Chart 1. It should be emphasized that during this period his temperature did not exceed 38.5 C. No toxicity developed. The pulse was of good quality, urinary output remained normal, and jaundice did not develop. Because of limited treatment of the burns on admission, the burned areas became grossly infected and were treated with daily saline tubs. After the first week the temperature began spiking daily to 39 or 40 C. because of the infection. Granulations gradually developed over the burned area, and these were grafted with Reverdin grafts from the thighs. In spite of marked improvement in the condition of the burns, the patient developed septicemia on the twenty-sixth hospital day. Blood cultures at that time showed a heavy growth of Bacillus aerogenes, and the patient died in spite of supportive therapy.

This patient survived the initial period of very extensive burns only to succumb later to cachexia and infection. He received large amounts of sulfa-

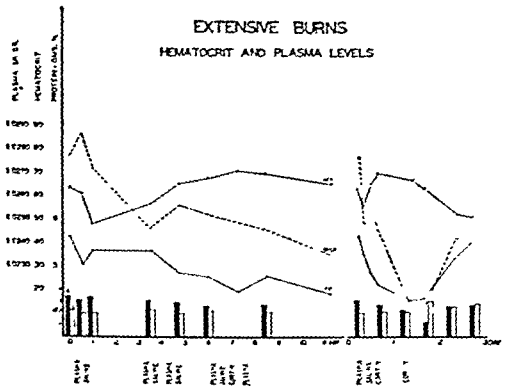

CHART 3

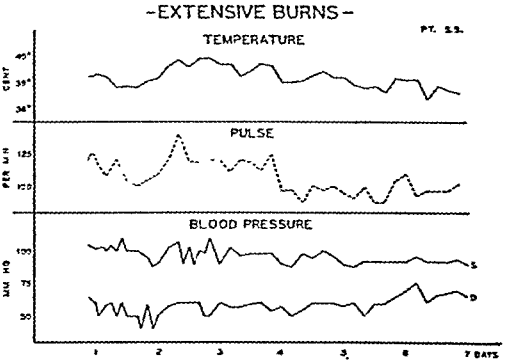

CHART 4

and was able to continue taking fluids and food by mouth. The blood pressure remained normal. The plasma specific gravity, the red cell hematocrit, and the blood protein levels are recorded in Chart 2. The urinary output remained normal, and toxic symptoms other than fever, on the third hospital day, did not develop. The temperature returned to normal on the fifth hospital day and remained so thereafter. In this instance eighteen hours were consumed before the burned areas had become dry with the sulfadiazine in triethanolamine therapy. There was extensive swelling of the soft tissue beneath the burned areas, but no peripheral edema developed. The subsequent course was uneventful. On the fourteenth hospital day the eschar was removed from the burned surfaces under general anesthesia, the third-degree areas were grafted with split-thickness grafts, and the second-degree areas were treated with vaseline gauze and compression dressings. The patient was discharged on April 16, 1942, with the burns essentially healed and no contractures.

The three case histories above are typical of the more seriously burned patients who are seen. All had sufficient surface area involvement to cause death unless they were treated rigorously, but all three patients survived the period of shock, and all had minimal evidence of toxemia. The first patient died at the end of a month from septicemia, but the other two survived. The amount of fluid therapy which they received is recorded in Table 1. The hematocrit, plasma specific gravity, and total protein concentration are recorded for Cases 1 and 3 (Charts 1 to 4). Case 2 could not be followed in detail because no veins were available for venipuncture.

Case 1 received 5,800 cc. of plasma in three days, plus 7,500 cc. of saline. The blood pressure in this patient did not become stabilized for thirty-six hours, and during this period it seemed impossible that circulatory stability would be restored. However, after thirty-six hours his condition became satisfactory, and he did not appear toxic until infection had become a prominent feature at the end of the first week. He did eventually die of infection, but not until one month after injury, at a time when the so-called period of toxemia was well past. His urinary output was above 1,500 cc. during the first two weeks, and jaundice did not develop. He did, however, receive far too much saline, for the plasma specific gravity and total protein concentration fell alarmingly by the second day (Chart 3). If more plasma had been available, so much saline would not have been given. His calculated circulating plasma volume was replaced approximately twice in forty-eight hours; yet more plasma should have been given to maintain the plasma specific gravity. It is possible that less total fluid would have been required if a greater proportion of it had been plasma.

Case 2 also received a large amount of plasma, but, again, possibly too much saline, as the plasma specific gravity was low on the second day, and periorbital and peripheral edema developed. Case 3 was more nearly ideally treated. She received an amount of plasma corresponding to the total estimated circulating plasma volume and only 200 cc. of saline and distilled water. The plasma specific gravity, total protein concentration, and hematocrit remained within normal limits. She was conscious at all times, took fluids by mouth after the first day, and had a normal urinary output in spite of moderate fever the first five days. The blood pressure remained normal throughout the débridement as well as afterward. It must be remembered that while she was severely burned, the involvement was less extensive than that of Cases 1 and 2.

Table 2 indicates the amount of plasma that these patients should have received according to the method of calculation of Harkins, Black, and Elkinton *et al.* These 3 cases actually required far more than the calculated amount of

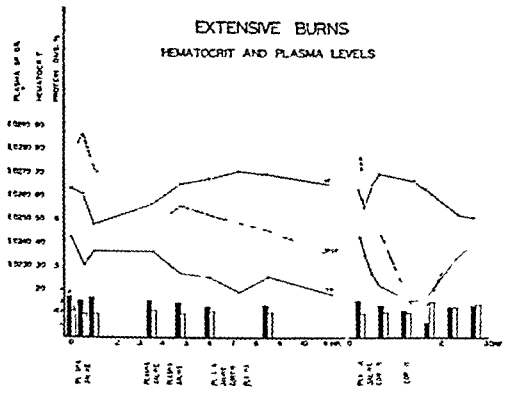

CHART 3

The blood pressure remained normal throughout the débridement as well as afterward. It must be remembered that while she was severely burned, the involvement was less extensive than that of Cases 1 and 2.

Table 2 indicates the amount of plasma that these patients should have received according to the method of calculation of Harkins, Black, and Elkinton *et al.* These 3 cases actually required far more than the calculated amount of

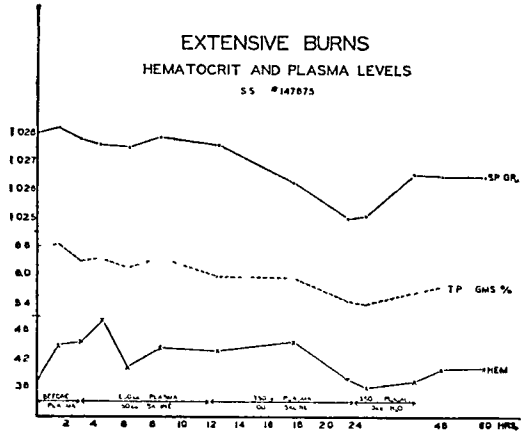

CHART 2

thiazole, was given repeated transfusions, and at one time received a continuous intravenous drip of 3½ per cent Amigen solution in 10 per cent glucose. Throughout his entire hospital stay his nonprotein nitrogen remained within normal limits. His blood plasma proteins were increased by plasma transfusions, and on December 31 were 6.6 Gm. per cent. These, however, gradually fell as he developed terminal cachexia and anorexia.

Case 2.—A. D. (R.M.H., No. 185292), admitted December 9, 1941, and discharged March 25, 1942. This patient was a 10-year-old girl whose clothes had been ignited from the kitchen stove shortly before admission. Her past history was noncontributory. On admission her temperature was 37.7 C., pulse 96, respirations 22, and blood pressure 110/68. The patient was a well-developed, well-nourished white girl. General physical examination was negative except for the burns. There were third-degree burns involving the entire chest, abdomen and thighs anteriorly and extending posteriorly on the left to involve half the posterior trunk. The burned area also involved the neck and face as well as both arms. By the method of Berkow, the burned area was estimated to involve at least 55 per cent of the body's surface. There was very marked edema of the tissue underlying the burned areas. The arms and thighs were increased to approximately twice their normal diameter. The patient was immediately given morphine, a leg vein was cannulated, and a transfusion of plasma and saline was begun. With the transfusion continuing, the burned areas were débrided in a tub. The patient was then placed on sterile sheets, dried, and the sulfadiazine in triethanolamine treatment (Pickrell) was started. During the débridement the patient's blood pressure remained within normal limits. She remained conscious and had very little pain. Two hours later the cannula in the vein plugged, and the blood pressure became unobtainable. Another vein was immediately cannulated, and with continuous transfusion of plasma, the blood pressure returned to normal. The amount of fluid that the patient received is tabulated in Table 1.

The blood pressure remained normal. On the third hospital day the temperature was elevated to 39 C., and the pulse was 120, but the patient continued to be alert, complaining of very little pain, and was able to take fluids and food without nausea. It required about twelve hours for the burned area to become adequately covered with the sulfadiazine eschar. The red blood count on the evening of admission was 5.33 million and the hemoglobin was 13.5 Gm. (after plasma and saline). On December 10, 1941, the red blood count was 5.25 million; hemoglobin, 13.5. On December 11, 1941, the red blood count was 4.2 million, and at this time the plasma was discontinued and the patient was given whole blood transfusions. After the third day the patient did not require further plasma transfusions, but she was given small blood transfusions at frequent intervals. Beginning on the sixth hospital day the patient received sulfadiazine by mouth, and the blood level varied between 5 and 7 mg. Her general condition remained good following this, and, although she lost weight, her appetite was fairly good. The burn over the trunk remained fairly clean, but that over the arms became infected. The eschar was removed thirteen days after admission, and the granulating areas were grafted daily with Reverdin grafts performed under local anesthesia. Because of the extensive surface area involved, it was impossible to obtain sufficient skin to use split-thickness grafts. The patient was discharged from the hospital on March 25, 1942. At the time of discharge there was a contracture of the neck, left axilla, and left groin which will require future plastic operations.

Case 3.—S. S. (R.M.H., No. 147675), admitted February 4, 1942, and discharged April 16, 1942. The patient was an 8-year-old girl who was admitted after extensive burns of the body from ignited clothing. The burn had been covered with butter and olive oil prior to admission, and a tannic acid compress had been applied by the ambulance attendant. Her past history was nonessential. On admission the temperature was 37.6 C., pulse 110, and blood pressure 106/64. The patient was alert, having very little pain. The general physical examination was negative except for the burned areas. There were second- and third-degree burns over the right side of the trunk and back, involving also the right thigh and the right arm. According to the method of Berkow, it was estimated that 35 per cent of the body's surface was burned. On admission, hemoglobin was 14.1 Gm. The white blood count was 21,700. Plasma specific gravity was 1.0280, and the red cell hematocrit was 39.1 per cent. The patient was immediately started on shock therapy although at this time blood pressure, hematocrit, and hemoglobin were normal. A continuous intravenous drip of whole plasma was started, morphine was given, and the burned areas were débrided in a tub. Then the patient was placed on sterile sheets and sulfadiazine in triethanolamine was applied to the burned areas. With continuous plasma therapy she remained conscious and cooperative

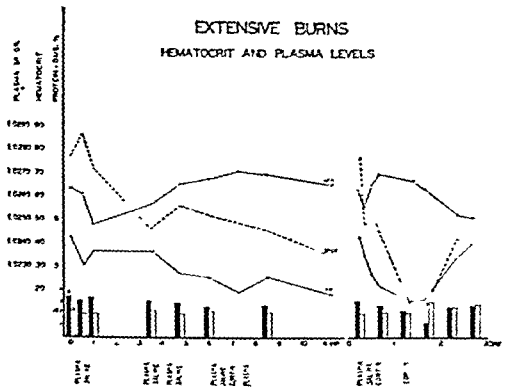

CHART 3

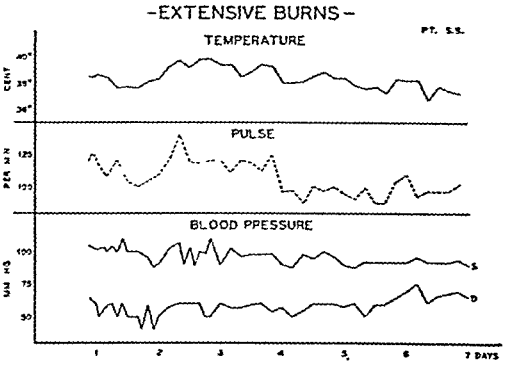

CHART 4

and was able to continue taking fluids and food by mouth. The blood pressure remained normal. The plasma specific gravity, the red cell hematocrit, and the blood protein levels are recorded in Chart 2. The urinary output remained normal, and toxic symptoms other than fever, on the third hospital day, did not develop. The temperature returned to normal on the fifth hospital day and remained so thereafter. In this instance eighteen hours were consumed before the burned areas had become dry with the sulfadiazine in triethanolamine therapy. There was extensive swelling of the soft tissue beneath the burned areas, but no peripheral edema developed. The subsequent course was uneventful. On the fourteenth hospital day the eschar was removed from the burned surfaces under general anesthesia, the third-degree areas were grafted with split-thickness grafts, and the second-degree areas were treated with vaseline gauze and compression dressings. The patient was discharged on April 16, 1942, with the burns essentially healed and no contractures.

The three case histories above are typical of the more seriously burned patients who are seen. All had sufficient surface area involvement to cause death unless they were treated rigorously, but all three patients survived the period of shock, and all had minimal evidence of toxemia. The first patient died at the end of a month from septicemia, but the other two survived. The amount of fluid therapy which they received is recorded in Table 1. The hematocrit, plasma specific gravity, and total protein concentration are recorded for Cases 1 and 3 (Charts 1 to 4). Case 2 could not be followed in detail because no veins were available for venipuncture.

Case 1 received 5,800 cc. of plasma in three days, plus 7,500 cc. of saline. The blood pressure in this patient did not become stabilized for thirty-six hours, and during this period it seemed impossible that circulatory stability would be restored. However, after thirty-six hours his condition became satisfactory, and he did not appear toxic until infection had become a prominent feature at the end of the first week. He did eventually die of infection, but not until one month after injury, at a time when the so-called period of toxemia was well past. His urinary output was above 1,500 cc. during the first two weeks, and jaundice did not develop. He did, however, receive far too much saline, for the plasma specific gravity and total protein concentration fell alarmingly by the second day (Chart 3). If more plasma had been available, so much saline would not have been given. His calculated circulating plasma volume was replaced approximately twice in forty-eight hours; yet more plasma should have been given to maintain the plasma specific gravity. It is possible that less total fluid would have been required if a greater proportion of it had been plasma.

The blood pressure remained normal. On the third hospital day the temperature was elevated to 39 C., and the pulse was 120, but the patient continued to be alert, complaining of very little pain, and was able to take fluids and food without nausea. It required about twelve hours for the burned area to become adequately covered with the sulfadiazine eschar. The red blood count on the evening of admission was 5.33 million and the hemoglobin was 13.5 Gm. (after plasma and saline). On December 10, 1941, the red blood count was 5.25 million; hemoglobin, 13.5. On December 11, 1941, the red blood count was 4.2 million, and at this time the plasma was discontinued and the patient was given whole blood transfusions. After the third day the patient did not require further plasma transfusions, but she was given small blood transfusions at frequent intervals. Beginning on the sixth hospital day the patient received sulfadiazine by mouth, and the blood level varied between 5 and 7 mg. Her general condition remained good following this, and, although she lost weight, her appetite was fairly good. The burn over the trunk remained fairly clean, but that over the arms became infected. The eschar was removed thirteen days after admission, and the granulating areas were grafted daily with Reverdin grafts performed under local anesthesia. Because of the extensive surface area involved, it was impossible to obtain sufficient skin to use split-thickness grafts. The patient was discharged from the hospital on March 25, 1942. At the time of discharge there was a contracture of the neck, left axilla, and left groin which will require future plastic operations.

Case 3.—S. S. (R.M.H., No. 147675), admitted February 4, 1942, and discharged April 16, 1942. The patient was an 8-year-old girl who was admitted after extensive burns of the body from ignited clothing. The burn had been covered with butter and olive oil prior to admission, and a tannic acid compress had been applied by the ambulance attendant. Her past history was nonessential. On admission the temperature was 37.6 C., pulse 110, and blood pressure 106/64. The patient was alert, having very little pain. The general physical examination was negative except for the burned areas. There were second- and third-degree burns over the right side of the trunk and back, involving also the right thigh and the right arm. According to the method of Berkow, it was estimated that 35 per cent of the body's surface was burned. On admission, hemoglobin was 14.1 Gm. The white blood count was 21,700. Plasma specific gravity was 1.0280, and the red cell hematocrit was 39.1 per cent. The patient was immediately started on shock therapy although at this time blood pressure, hematocrit, and hemoglobin were normal. A continuous intravenous drip of whole plasma was started, morphine was given, and the burned areas were débrided in a tub. Then the patient was placed on sterile sheets and sulfadiazine in triethanolamine was applied to the burned areas. With continuous plasma therapy she remained conscious and cooperative

lating protein may become reversed because of the excessive loss of albumin, and if the blood plasma protein concentration is low, generalized edema will develop.

Many investigators now feel that the liver damage which occurs during the toxemic phase of burns is probably due to generalized anoxia. The oxygen saturation of the blood in shock is decreased and stagnation of blood in the liver and elsewhere in the body may result in cellular damage. If this theory is true, it may not be necessary to hypothesize the elaboration of a toxin from the burned area. This theory is supported by the observations here that severely burned patients who have received adequate replacement therapy exhibit minimal signs of toxemia.

The clinical results indicate that a burned patient loses a large amount of fluid into the tissues and vesicles very quickly. This loss of fluid may continue for several days, but the rate of loss gradually decreases. During the first twenty-four hours, the patient should receive whole plasma, and the amount should be governed by the hematocrit and the plasma protein level. *After twenty-four hours, less plasma is required,* and the replacement by half saline and half plasma is usually adequate. If the patient can take fluids by mouth, the parenteral fluid requirement will be reduced by half. At the end of forty-eight hours, the hematocrit is usually declining, and whole blood transfusions may be necessary. *Experience indicates that it is almost impossible to give too much plasma, but very easy to give too little.*

This closely controlled method of fluid therapy requires adequate laboratory facilities and constant attention. It would be impossible to do all of the procedures under conditions of battle or in hospitals without adequate laboratories. The practical application is that whole plasma should be administered continuously for the first eighteen to twenty-four hours in amounts sufficient to prevent hemoconcentration. The extensively burned patient requires plasma for at least forty-eight hours, but during the second day it may be diluted with equal parts of saline. The need for whole blood transfusions is indicated by a decline in the hemoglobin level. Patients treated in this manner will have a better opportunity of surviving the burn shock, and the toxemia will be minimized.

The role of the various blood substitutes in burn therapy has not yet been determined. The use of pectin as well as acacia may be of value. Acacia has the definite disadvantage of causing liver damage and should not be used. The most promising material seems to be the precipitated albumin, but it has not as yet been tested adequately. Plasma is becoming more readily available throughout the country, and for the present is the most adequate means of replacement therapy.

Conclusions

1. The immediate and adequate instigation of replacement therapy (fluid and protein) is the most important feature in the primary treatment of severe burns.

2. Replacement therapy should be carefully controlled by continuous observation of plasma specific gravity (protein) and hematocrit or hemoglobin.

3. The toxemia of burns will be minimized if not entirely prevented by adequate fluid and protein replacement.

4. The local treatment of the burn will vary with individual experience and will be guided by the condition of the patient.

Discussion

Dr. Walter A. Coakley, *Brooklyn*—In April, 1937, we published a paper on burns in the *American Journal of Surgery.* This paper was based upon a series of 300 patients, all of whom were burned severely enough to warrant hospitalization. In that paper we stated that the replacement of fluid loss and early skin grafting were important in preserving the life and in the healing of the burned patient and that no single local treatment should be the accepted one. Now, five years later, we are of the same opinion.

The treatment of the burned patient in recent years has undoubtedly decreased considerably the mortality and morbidity. This can be attributed not to any single method or drug in use (as many

plasma to maintain their hematocrit and plasma protein concentration at an approximately normal level. Two other cases required approximately the theoretic amount of plasma, but they were not so extensively burned.

These patients must be followed very carefully even after the initial period. The hemoglobin usually begins to decrease about the third day, and this condition should be treated with whole blood transfusions. The following laboratory investigations should be made in order to control the subsequent course:

1. Daily red blood count and hemoglobin and hematocrit.
2. Daily urine; especially specific gravity, albumin, and red blood count.
3. Plasma specific gravity; and, if possible, this should be checked by chemical analysis of total protein, albumin, and globulin at frequent intervals.
4. Blood nonprotein nitrogen, icterus index, and chlorides.

The entire premise of fluid therapy depends on the daily evaluation of the patient and the replacement of plasma, whole blood, water, or electrolytes as may be required.

Local Treatment of Burn

The local treatment of the burn will vary with individual preference and experience. However, the general principles may be outlined as follows:

1. The patient who has 15 per cent or more of his body surface burned should receive shock therapy immediately following admission. A vein should be cannulated and a continuous injection of plasma should be started, preferably using a Murphy drip bulb.
2. Débridement. If adequate shock therapy is started early, débridement of the burn can be done without delay in all except the very extensive burns. Many methods of débridement have been advocated, varying from a simple removal of loose devitalized tissue to vigorous débridement under anesthesia. A burn should be treated as a traumatic wound, and when seen early can be converted from a contaminated to a clean wound. This requires the use of operating room technic with sterile gowns and drapes and gentle scrubbing of the area with removal of necrotic tissue. The dressing used should protect the area from subsequent contamination, if possible. This can best be done under light general anesthesia if the patient is in satisfactory condition.
3. The most common type of dressing is by means of an eschar forming agent. Tannic acid[14] or tannic acid and silver nitrate[15] are widely used, and have greatly decreased the mortality of burns. It must be emphasized that an eschar only prevents the external loss of fluid, and does not prevent the loss into the tissues beneath the burn. Infection is likely to occur if thorough débridement has not been done. The method advocated by Pickrell,[16] using sulfadiazine in triethanolamine, has the advantage of reducing infection, but the definite disadvantage of requiring from eighteen to twenty hours to form the eschar. The compression method of Allen and Koch[17] and of Siler[18] is a rational treatment of burns utilizing the principles of traumatic wound healing. Siler[18] has found that his patients seem to require less plasma, indicating that uniform compression may reduce the fluid loss into adjacent tissue.
4. The proper splinting of burned extremities and the early grafting of third degree burns is of paramount importance.

Discussion

The fluid which fills the vesicles of a burn is not whole plasma, but contains mainly albumin. The average content of the vesicle fluid has been found to be: total protein, 3 to 4.5 Gm. per cent, of which albumin constitutes 80 per cent or more. The albumin-globulin ratio of the circu-

lating protein may become reversed because of the excessive loss of albumin, and if the blood plasma protein concentration is low, generalized edema will develop.

Many investigators now feel that the liver damage which occurs during the toxemic phase of burns is probably due to generalized anoxia. The oxygen saturation of the blood in shock is decreased and stagnation of blood in the liver and elsewhere in the body may result in cellular damage. If this theory is true, it may not be necessary to hypothesize the elaboration of a toxin from the burned area. This theory is supported by the observations here that severely burned patients who have received adequate replacement therapy exhibit minimal signs of toxemia.

The clinical results indicate that a burned patient loses a large amount of fluid into the tissues and vesicles very quickly. This loss of fluid may continue for several days, but the rate of loss gradually decreases. During the first twenty-four hours, the patient should receive whole plasma, and the amount should be governed by the hematocrit and the plasma protein level. After twenty-four hours, less plasma is required, and the replacement by half saline and half plasma is usually adequate. If the patient can take fluids by mouth, the parenteral fluid requirement will be reduced by half. At the end of forty-eight hours, the hematocrit is usually declining, and whole blood transfusions may be necessary. *Experience indicates that it is almost impossible to give too much plasma, but very easy to give too little.*

This closely controlled method of fluid therapy requires adequate laboratory facilities and constant attention. It would be impossible to do all of the procedures under conditions of battle or in hospitals without adequate laboratories. The practical application is that whole plasma should be administered continuously for the first eighteen to twenty-four hours in amounts sufficient to prevent hemoconcentration. The extensively burned patient requires plasma for at least forty-eight hours, but during the second day it may be diluted with equal parts of saline. The need for whole blood transfusions is indicated by a decline in the hemoglobin level. Patients treated in this manner will have a better opportunity of surviving the burn shock, and the toxemia will be minimized.

The role of the various blood substitutes in burn therapy has not yet been determined. The use of pectin as well as acacia may be of value. Acacia has the definite disadvantage of causing liver damage and should not be used. The most promising material seems to be the precipitated albumin, but it has not as yet been tested adequately. Plasma is becoming more readily available throughout the country, and for the present is the most adequate means of replacement therapy.

Conclusions

1. The immediate and adequate instigation of replacement therapy (fluid and protein) is the most important feature in the primary treatment of severe burns.

2. Replacement therapy should be carefully controlled by continuous observation of plasma specific gravity (protein) and hematocrit or hemoglobin.

3. The toxemia of burns will be minimized if not entirely prevented by adequate fluid and protein replacement.

4. The local treatment of the burn will vary with individual experience and will be guided by the condition of the patient.

Discussion

Dr. Walter A. Coakley, *Brooklyn*—In April, 1937, we published a paper on burns in the *American Journal of Surgery.* This paper was based upon a series of 300 patients, all of whom were burned severely enough to warrant hospitalization. In that paper we stated that the replacement of fluid loss and early skin grafting were important in preserving the life and in the healing of the burned patient and that no single local treatment should be the accepted one. Now, five years later, we are of the same opinion.

The treatment of the burned patient in recent years has undoubtedly decreased considerably the mortality and morbidity. This can be attributed not to any single method or drug in use (as many

proponents of certain drugs would like to make us believe), but rather to a more basic and fundamental understanding of the disrupted physiology which results. This includes many intricate and complex pathologic changes, not only locally, but throughout the vascular system, and includes many tissues and vital organs quite remote anatomically from the site of the burn.

Any treatment or series of treatments which takes all of these changes into consideration and tends to offset them and to keep the body in a more normal state of equilibrium is good treatment. Conversely, any treatment which disregards these fundamental changes, regardless of how zealously and enthusiastically it is carried out, is poor treatment.

According to the Bible, the human body is "fearfully and wonderfully made" and one realizes this when he undertakes the study of water balance in the human mechanism; for the human body is essentially composed of water, which constitutes more than 70 per cent of protoplasm, the structural basis of organic life.

It is necessary to the life of every living cell, and the digestive juices, blood, lymph, urine, etc., are all more than 90 per cent water.

Almost every chemical or physical phenomenon occurring in the body depends directly or indirectly upon the presence of water.

Goldstein has shown that every kilogram of body weight contains 0.6 to 0.7 Kg. of water; thus a child weighing 50 pounds net really weighs only 15 to 20 pounds of solids, but weighs 30 to 35 pounds in water content. It is obvious that any shift in water balance results in physiologic and pathologic changes.

One must carefully consider water balance if he is to treat burns according to proper chemical procedure, for it is the fluid shift which is the cause of secondary shock, and it is this secondary shock which is dangerous to life. Very few deaths occur in the stage of primary shock, which is probably due to overstimulation of multiple nerve endings.

This "fluid shift" is due to a local loss of fluid into the tissues, principally from leakage into the burned areas. The fluid has about the same concentration as blood plasma, its chloride content being a little higher than that of plasma. Its sugar and nonprotein nitrogen contents are about the same, while its protein content is at least 80 per cent of that of plasma. This latter fact is important and should be kept in mind.

The so-called fluid shift is accompanied by a decrease in blood volume with an associated reduction in the cardiac output, plus considerable fall in blood pressure. There is a resultant concentration of the blood, accompanied by a rise in hemoglobin, with a distinct decrease in blood chlorides. We had one child on our service with a hemoglobin of 160 per cent and a red blood count of 8,500,000.

It has been shown by experiment, using the rabbit, that this fluid shift reaches its height in the first twenty-four to thirty-six hours, and that under experimental conditions a burn of one-sixth of the body area gives a fluid loss of 70 per cent of the total blood volume in twenty-four hours. If these figures are applied to the human being, it will be seen that a man weighing 65 kilograms and having a blood volume of 5,000 cc., would suffer the staggering loss of 3,500 cc. of fluid in the first twenty-four hours. This extreme blood concentration takes place also in superficial burns.

How, then, shall we compensate for this fluid loss and keep the blood content up to normal? Obviously, only by forcing fluids, and, they can be forced properly only by keeping in mind what we learn from frequent blood pictures.

The intravenous route is the path of choice, and saline and glucose, Ringer's solution, and blood plasma are the useful replacements.

The needs of the patient must be kept in mind. Approximately 2,000 cc. to make up for insensible loss; 500 cc. for loss by the intestinal tract; 1,500 cc. for kidney function to dilate chemicals for excretion. An added amount should be used if vomiting, diarrhea, or fever are present.

Fortunately in diarrhea an attempt is made to preserve the blood volume by attracting fluids from the tissue spaces, owing to the raised osmotic pressure of the plasma proteins.

One must be careful in his attempts to replace this fluid loss, as the excessive use of replacements may cause a generalized edema, with a resultant extra load to the already overburdened patient. One should, therefore, always keep his acid-base equilibrium in mind, and it is well to remember that if we give a patient 5 liters of fluid in one day, using saline as a vehicle, we are administering not only 5,000 cc. of water but also about 45 Gm. of salt, which is about ten times the amount normally used by the body in one day.

Holdame has reported edema following the ingestion of 40 Gm. of sodium chloride. We, nevertheless, are faced with the problem of replacing excessive chloride losses, and saline intravenously is the best means we have at the present time. We not only replace the chlorides, however, for it is the sodium ion, not the chloride, that holds the water. If this be so, then the administration of excessive quantities of fluids containing sodium chloride is dangerous, for fluid-carrying sodium must be stored in the body, thus contributing to generalized edema.

Hypoproteinemia

With the extravasation of fluids into burned tissues the serum protein is lowered. We know that nutritional edema is in part due to the lowered colloidal osmotic pressure, which is the result of a lowering of the serum protein. Therefore, if we are to keep the body fluids up to normal without "waterlogging" the patient, it is well to keep up his serum proteins.

This is very important because, as we know, the function of the albumin and globulin is to: (1) retain blood in the capillaries, (2) help maintain blood volume, (3) regulate interchange between the blood and tissue spaces, and (4) influence filtration in the kidney glomeruli. The last calls attention to the relation of serum protein loss in burns to similar conditions in nephrosis, the time element of course, being different.

How, then, shall we restore the serum proteins? We have found plasma and amino acids parenterally most useful and would call your attention to the soy bean. A diet of soy bean flour is ideal because of its rapid conversion into blood protein.

As to what to apply to the burned area, we have used the following: tannic acid, from 5 per cent to 10 per cent; gentian violet, 1 per cent; tannic acid, 5 per cent, and gentian violet, 1 per cent, combined; a tannic acid jelly; picric acid ointment; silver nitrate solution, 10 per cent, and irradiated petroleum; and a codliver oil ointment. Each is useful; none can be universally used. Our preference has been for the freshly prepared tannic acid and gentian violet mixture. This is sprayed on the burned areas every fifteen minutes and dried with a hot-air blower similar to that used in hairdressing establishments. This is done for a period of two hours, then at longer intervals for the next twenty-four hours. A firm, soft coagulum is formed, pain is relieved, fluid loss is decreased, body heat is preserved, and infection is minimized. The patient is at all times upon a sterile sheet, and is under an electric light cradle, where a constant temperature of 99 F. is maintained.

We are now using $2^1/_2$ per cent to $3^1/_2$ per cent sulfadiazine in 8 per cent aqueous solution of triethanolamine. This makes a soft, pliable eschar, but every patient on whom we have used it complains of more or less pain. To the surgeon who has had experience in treating burns, there is obviously no panacea as far as the local treatment is concerned. We have had pleasant experiences where there has been suppression of urine in the use of short-wave diathermy applied to the kidney region for twenty minutes every two hours for twenty-four hours. This seems to aid in increasing kidney function. Of course, we cannot too strongly urge the early, frequent, and unstinting use of blood plasma.

CONSCIENTIOUS OBJECTOR PROBLEM ONE OF RE-EDUCATION

Pointing out that numerically the problem of the conscientious objector is of little importance, the *Journal of the American Medical Association* for May 15 says that "From an ethical point of view the problem is one of re-education, of instilling in the individual the appreciation of his civic responsibilities, and of awakening in him a feeling of national conscience and national unity. . . . .

"At the commencement of the first World War there were in the United States, according to D. E. Hoag, about 300,000 males classified as conscientious objectors. About 30 per cent of these were of military age. In June, 1918, the Surgeon General's Office sent out to various camps a special form for examination of conscientious objectors. Mark A. May, in his report to the Office of the Surgeon General, presented the then available information concerning the intelligence, education, grounds of objection, and social and political history of conscientious objectors. The report covered twenty camps and represented about 1,000 objectors. May pointed out that the intelligence of the conscientious objectors, as measured by the Army mental tests, was, on the average, above that of the white draft of the Army as a whole. At least 97 per cent of the men had sufficient intelligence to know what they were doing. About 50 per cent were Mennonites; less than 10 per cent of these went beyond the eighth grade. The 12 per cent of the total series who reached college were either Socialists, Dunkards, or Friends. The various religious sects involved, with the possible exception of the Friends, believe in the literal interpretation of the Scriptures. The grounds of objection were, in general, three: religious, social, and political. The religious objector makes his appeal to the Bible, church creed, and to conscience; the social objector to individual freedom; the political objector usually bases his objection on the ground of alien citizenship.

"Harry Stalker of Edinburgh reports the results of an examination of 12 persons with psychiatric states who were also conscientious objectors. They represented three types of personalities. . . . . The meager reports from continental European countries, whose laws do not provide for conscientious objectors, deal almost entirely with persons mentally involved. Thus, among 31 objectors studied by Peter Schulthess there was only one sane person; 15 were psychopaths, 4 of them feebleminded, and 6 schizoid (split personality). . . . .

"Prompt discharge from the army and appropriate institutional treatment are the effective solutions of the problem of the psychopathic objector. The problem of the sane objector is much more complicated. There is, of course, no intention on the part of our government to compel the genuinely conscientious religious objector to enter the armed services, for that would amount to violation of his constitutional rights, something we must guard against even in time of war. However, the degree of sincerity of his beliefs is difficult to determine. In the first World War, of 2,100 persons 1,500 were found to be sincere objectors and recommended for farm or industrial furloughs; 219 were found to be sincere objectors to combatant but insincere as to noncombatant service; 156 were found to be sincere objectors to combatant but willing to accept noncombatant service, 15 were found to be sincere objectors to combatant service but willing to work in reconstruction hospitals, and 122 were found to be insincere as to both combatant and noncombatant service.

"In this war many of our conscientious objectors are young men of good education, often of good family training. No doubt the same proportions prevail in relation to religious and political objectors as in previous wars. Fortunately the problem was given attention early by the Selective Service Administration, so that today many of these boys are engaged in occupations in the field of medicine, in hospitals, and in similar activities, where they are rendering a genuine service to the war effort. A number have volunteered to serve as subjects for important experiments in testing the value of life-saving technics in the services to be given to our troops in China and in the South Pacific. There are functions which the conscientious objectors can perform and for which many of them have already volunteered without demanding participation in combat."—*A.M.A. News*

UROLOGY IN INDUSTRY

GEORGE E. SLOTKIN, M.D., F.A.C.S., Buffalo

THE present popular conception of urology in industry is the belief that trauma, either by direct or indirect violence, is the major factor creating disease conditions. This fallacy was warranted because of the meager information emanating from industry and directly affecting the urinary tract. Trauma was and still is of prime importance but extrinsic factors must be seriously considered, and this discussion is based on these premises.

An analysis of industrial cases seen in the past five years disclosed the amazing information that of pathologic changes in the kidney, ureter, and bladder, 95 per cent are not directly traumatic. From this analysis it was concluded that, in addition to direct and indirect trauma following accidents, toxemias of clinical and bacterial origin were potent pathologic factors in causing disease of these organs. These clinical changes were created by the inhalation of gases, the by-products of acetylene welding and soldering, with the inhalation of ammonia, arsenic, hydrochloric acid, and lead. The type of lesion created ranged from acute hemorrhagic nephritis and amyloid nephrosis to aggravation of a previously existent chronic nephritis and the secondary constitutional symptoms resulting therefrom. The same lesions were noticed from inhalations following the use of cleaning fluids, the most potent and toxic of which is carbon tetrachloride marketed under various popular labels without suitable and sufficient warning regarding its use.

Because of the present trying conditions, industry is attuned to an unusual peak of maximal efficiency, and the manufacture of chemicals and their uses should be common knowledge to the physician in combating the hazards that result from exposure to the substances and disturb the efficient organization of industry by physical breakdown. The Niagara Frontier area is today the largest chemical center in the world, with thousands of highly trained employees. Without these chemical products our entire industrial program would collapse; therefore, the recognition of the relation of these various chemicals to diseases of the urinary tract is of paramount importance.

There has been a most commendable cooperative effort in these industries to prevent hazards by using this knowledge of the chemicals and their actions, and this preliminary knowledge was instrumental in reducing an occupational incidence of the development of carcinoma of the bladder in 12.8 per cent of the employees to complete freedom of new cases in the last year. Such advancement can be accounted for only by the diligent periodic examination of men in these industries and by the fullest cooperation by the employer in isolating the products in separate buildings and revising the method of manufacture to such an extent that at the present time contamination by inhalation is infinitesimal. A similar study and coordination of effort between the manufacturer and the physician would, I am sure, result in further reduction in the incidence of urinary changes from volatile gases if such changes were detected and treated accordingly.

Bacterial invasion has also been a prominent cause of urinary changes involving the kidney and bladder. Workers in grimy, dusty occupations, particularly heavy industry and foundries, tanners, and meat packers, through simple abrasion of the skin and by blood stream or lymph contamination, have developed secondary nephritis and pyelonephritis by indirect invasion. Serious consideration must be given to the development of a perinephritic and paranephritic abscess secondary to a folliculitis, boil, or carbuncle, especially if these lesions occur in workers employed in types of industry in which contamination or infection of the skin is frequent. This is particularly important since the urinary lesion may develop months after the inception of the apparently simple superficial, nondisabling primary source of infection.

Trauma to the urinary tract is still an important consideration.[1] The lesions of the kidney from such trauma are divided into concussion, contusion, and rupture, and the type of lesion is not dependent upon the violence encountered. Complete rupture has followed a simple muscle strain that resulted from lifting a heavy object, in contradistinction to a simple concussion following a fall of 60 feet. My experience paralleled the excellent review of Priestley,[2] who found that 3 out of every 45 injuries to the kidney were caused by muscle pull alone and about 40 per cent were due to falls. The rest followed direct trauma. The diagnosis in these cases is made by the history, by pain, which occurred in 75 per cent of the cases, and by the development of hemorrhage with hematuria present in 95 per

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1942.

From the Department of Urology, Millard Fillmore Hospital, Buffalo.

clots were noted in 33 per cent of the cases. These findings, plus shock and the development of tumor, makes the diagnosis very simple. The most important factor involved is the surgical judgment for expectant or operative treatment. In Priestley's series, 34 per cent were operated upon and 66 per cent were treated expectantly. In severe injuries, early surgery is a lifesaving procedure and if possible should be performed on the same day that the injury is received. When delay is the method of choice, bleeding is the important factor. In these cases, intravenous diodrast is of extreme usefulness and is preferred to cystoscopy. The type of operation, of course, depends upon the type and severity of the trauma. Where no surgery is employed, the possibility of latent secondary infection or the development of a stone should be a considerable factor in the final closing of the case.

Injuries to the ureter may or may not be involved with the kidney and are very rare. In an eleven-year survey by Rusche[3] at the Los Angeles Hospital only one case of ureter injury due to external violence was noted. McKenna,[4] however, noted that the ureter was severed completely with severance at the pedicle and completely with minor injuries. The repair was made by introducing a catheter to maintain the ureter's continuity. His preference in the diagnosis is also by intravenous means rather than by retrograde treatment that will lessen the hazard of contamination. This contention can be subscribed to.

Injuries of the bladder usually occur when the bladder is full and are associated and involved with fracture of the pelvis. A penetrating wound of a splinter from the pubis or ischium is driven into the bladder with consequent rupture. One case was noted of a direct penetrating wound; the patient fell 10 feet into a pit, and the bladder was penetrated suprapubically with a spike 4 inches long without injuring the peritoneum or pelvis. Fortunately, his bladder was full and the penetrating object acted as a trocar. Peacock's[5] series of cases of rupture of the bladder over a period of thirty-four years analyzes 28 cases, 18 in men, 10 in women. Industry accounted for 50 per cent of the ruptures and automobiles for the other 50 per cent. In hazardous occupations, loggers ranked at 25 per cent and laborers at 11 per cent. In 85 per cent of the cases, fractured pelvis also occurred. In a series of 113 cases of fractured pelvis, there were 13 tears of the bladder with 10 ruptures. There was a total mortality of 20 per cent in Peacock's series. His recommendation is prompt and early cystotomy as a lifesaving procedure before secondary repair. This percentage is confirmed in my series of industrial ruptures. Of course, the number seen was smaller, but the procedure followed was the same—simply treatment of shock, cystotomy for diversion of the urinary stream, and no attempt at any secondary repair, which followed convalescence.

One of the great controversial subjects is the relation between injury and ptosis of the kidney. Many a wearisome hour has been spent by physicians in civil and compensation courts on this mooted question. Many theories have been advanced as to the causal relationship between such factors. Perhaps a clarification at this time might be in order. My belief on this matter, of course, is not dogmatic, nor do I expect it to be the final word and accepted as authoritative. Every practicing physician and urologist has his own theories regarding this relationship. I wish simply to state facts as they have arisen in actual cases and the deductions which I have derived from this observation.

In industry, ptosis of the kidney is believed to occur as a result of force or blows dislodging the kidney from its normal bed and position. The kidney is one of the deepest-seated of all organs, lying close to the lumbar spines and protected by the heavy lumbar muscles with a pad of fat, the capsule of Gerota, acting as a buffer. Its natural support is poor, but adequate—the renal pedicle proper, its own fatty capsule, the abdominal pressure with some of its fat, and proper posture together with the minor ligaments of the hepatoduodenal on the right side and the phrenicorenal on the left side. I have always maintained and believed that just as a single blow is never of sufficient violence to cause carcinoma, so a blow is not strong enough to cause a displacement of a kidney unless at the time of the injury or fall sufficient disturbance took place first to create a severe contusion or laceration. If this, therefore, is necessary, the first symptoms that should be noted are evidence of renal injury. Unless there is such evidence at the time of injury, according to our diagnostic ability, the kidney cannot, as a result of such a single blow, be dislodged, assuming, however, that it had been in the proper position to begin with.[6] This premise is based on the fact, not theory, that individuals of moderate stature have fallen from heights of 60 feet without renal displacement. Athletes indulging in strenuous sports, of which I believe basketball and wrestling are the most violent, have, in my experience, never created a single case of ptosis. When such a ptosis does occur following an injury, there must have been involvement of the kidney first. It is also possible that the kidney was ptosed before the alleged injury but was symptomless through proper drainage.

If, as a result of such injury, the kidney becomes fixed from secondary inflammation or adhesion bands, with the development of an inability for the kidney to empty properly (i.e., pyelectasis which can be determined only by intravenous diodrast or retrograde cystoscopy in the upright position), then can one subscribe to the aggravation but not the creation of a ptosis from such an injury.

Renal ptosis has never been seen in patients of good musculature and proper posture. It is seen only in the asthenic, indolent patients, especially women, who are underweight and who have poor muscle tone. Ten cases are seen in women for every one in men and very few are found that involve the left side. While the diagnosis can be made readily by retrograde cystoscopy in the upright position, intravenous diodrast and serialograms with the Jarre-Sinex timer to determine the emptying time of the pelvis are, nevertheless, of maximal importance. A great number of cases will be seen that are symptomless in spite of the position of the kidney. Unless positive findings are made of displacement with retention and slow emptying time, the kidney is considered symptomless.

What is the importance attached to this study to industry? Because of the prevalence of this disease among under-developed, dieting young women, who are today supplanting men in industry, its importance cannot be overemphasized. The morbidity of this condition will undoubtedly rise because of the large influx of women into positions requiring more than simple clerical attention. Women are today being used in the airplane, chemical, and machine tool industries. As yet heavy industry has not had occasion to supplant the men, but at the present rate of growth of the armed forces women may be found even in this type of work. It is important that a physical examination include not only an x-ray of the chest and a urinalysis, as is routine today, but also a plain plate of the abdomen to determine the size, shape, and position of the kidneys, as a prophylaxis against the increased incidence of industrial ptosis.

This same depletion of young men and adults from industry has created another series of problems which will lead to grave consequences, as has already been seen in a few instances. Older men are being recalled to assume positions that are being evacuated through selective service. Men of 55 and over who were discharged because of the supposed hazard attendant upon their age are riding the crest of labor in all its forms. Moore[7] has shown that in all men over 50, carcinoma of the prostate is present in from 14 to 16 per cent of cases. This ratio has been verified by many investigators. One does not require much imagination to appreciate the number of cases of alleged back injuries, sacro-iliacs, and sciaticas that will arise in this large percentage of patients who are suffering from potential metastatic carcinoma. This changing trend of events places another burden on the examining physician and on the urologist who will eventually see these cases. For years, I pleaded with the insurance carriers for routine urinalysis on employees. Finally this was accomplished after the hazards of occupation with reference to the urinary tract were realized. It will now be necessary to supplement this examination with a prostatic examination in all men over 50, or perhaps a routine acid-alkaline phosphatase blood determination. Henline,[8] in a recent communication, clarifies this situation and emphasizes the importance of a careful rectal examination of the prostate, and because of the marked instances of carcinoma in men over 50, even justifies a biopsy in cases of doubt

Summary

Industry today is faced with a major problem beyond that of trauma. A thorough knowledge of the chemistry of industry and its relation to the urinary tract is required for proper morbidity and therapeutic results. The cooperation of industry with medicine has resulted in a marked improvement of working conditions for employees, the recognition of afflictions of the urinary tract relative to industry and their proper care. Because of the prevalence of ptosis in young women of today whose industrial activities are extended to heavier industry, more thorough examination should be required to discount the possibility of a subsequent claim for ptosis. Since this condition is insidious in its onset, the acute manifestations occur only with severe injury and renal changes. Finally, with the large percentage of older men replacing inductees in industry, the high incidence of carcinoma must be borne in mind and an examination before employment must be emphasized.

Discussion

Dr. Walter G. Hayward, *Jamestown, New York*—Dr. Slotkin's report of the reduction in the development of carcinoma of the bladder from 12.8 per cent to 0 per cent in one year is truly remarkable.

Although a number of our local plants are engage

in war production work, none of them is engaged in the use of aniline dyes, so that that danger is not present in my community. I should like to hear him explain in detail the exact methods of safeguarding these men.

The development of peri- and paranephritic abscess following boils occasioned by work in industry has been a source of considerable argument and litigation in my locality. I can recall one case, unquestionably due to occupation, that a Pennsylvania court disallowed.

As to the treatment of kidney trauma, you will all recall, not so many meetings ago, the debate that was held on whether to operate promptly or to wait and treat expectantly. I think every urologist has his mind pretty strongly made up on the subject, and it is my own feeling that no set rule can be laid down, but each individual case must be treated as such.

Ptosis of the kidney, as regards accident, is a headache to any urologist who has been called on the stand to testify. Personally, I have not seen a case that I have felt could be attributed to accident. In some cases, we were fortunate enough to locate x-rays of the claimant that had been taken prior to the accident, disproving his claim, and in others, pre-existing kidney lesions were found.

A few years ago Dr. Edward McCague, professor of urology at the University of Pittsburgh, wrote an interesting article on the occurrence of urinary calculi secondary to trauma. This was especially prevalent following fractures of the femur and fractures of the spine. However, he admitted in his article that although a careful survey had been made in their rather expensive service, comparatively few cases had occurred. This interested me enough so that I immediately called it to the attention of our orthopaedic men, and from that time on, a fairly close check was kept. This has not been possible with private patients, on whom seemingly unnecessary x-rays would place a burden, but it has been done on a number of the city cases, and so far we have been unable to find any calculi developing secondary to fractures. One case of my own, a fractured pelvis, developed a bacillus proteus infection and promptly showed bladder calculi.

Dr. George F. Hoch, *New York City*—Dr. Slotkin showed that few nephroptoses are due to trauma, in which I concur. Of 214 cases noted by Kelly, only 13 had a traumatic history.

DR. STRECKER IS CONSULTANT TO SECRETARY OF WAR

Dr. Edward A. Strecker, of Philadelphia, president of the American Psychiatric Association, has been named special consultant to the Secretary of War for the Air Forces of the United States Army, according to an announcement by the Committee on Public Education of the American Psychiatric Association.

In this capacity, Dr. Strecker will act as adviser to War Secretary Henry L. Stimson on all questions relating to psychiatry in the Air Forces. Serving as a civilian adviser, Dr. Strecker will be on call at all times by the War Department.

The appointment marks the second special consultant's post for Dr. Strecker. A while ago, he was named consultant in psychiatry to the Surgeon General of the U.S. Navy, in which capacity he acts as adviser in psychiatry to the Navy's Bureau of Medicine and Surgery.

Dr. Strecker recently established the first intensive training school for naval medical officers in Philadelphia. All of the medical and hospital facilities throughout the city are cooperating in this program, three months in length, which has already graduated more than a score of officers. A third class is in training.

Dr. Strecker has had extensive military experience. In World War I he held the rank of Major in the Army Medical Corps, as division neuropsychiatrist for the 28th Division in France. He became known as an authority on the military psychiatric disability formerly known as "shell shock."

Dr. Strecker is professor and head of the department of psychiatry at the University of Pennsylvania's Graduate School in Philadelphia, and the Medical School of the same university. He has been medical and clinical director of the Pennsylvania Hospital's Department of Nervous and Mental Diseases since 1917. He is chief of service and consultant at the Institute for Mental Hygiene of the Pennsylvania Hospital, and consultant for Bryn Mawr College and the U.S. Veterans' Bureau.

Author of a best-selling medical work on alcohol called *Alcohol—One Man's Meat*, Dr. Strecker has also made special researches on abnormal behavior in children. He is staff neurologist for the Pennsylvania, Philadelphia, and Germantown Hospitals.

In 1939, Dr. Strecker was selected to deliver the Salmon Lectures on Psychiatry and Mental Hygiene. He served as clinical professor of psychiatry and mental hygiene at Yale University in New Haven, Connecticut, from 1926 to 1932.

As president of the American Psychiatric Association, the oldest association of medical specialists in the country, he will preside at that group's centennial anniversary next spring in Philadelphia, site of the Association's founding.

HANDBOOK FOR MEDICAL LIBRARIANS PUBLISHED

After three years' cooperative effort on the part of the Medical Library Association and the American Library Association, the first comprehensive work for medical librarians has been published. It is entitled *Handbook of Medical Library Practice* and is a compilation of articles contributed by leading authorities. Its editor is Janet Doe, assistant librarian of the New York Academy of Medicine.

If, as a result of such injury, the kidney becomes fixed from secondary inflammation or adhesion bands, with the development of an inability for the kidney to empty properly (i.e., pyelectasis which can be determined only by intravenous diodrast or retrograde cystoscopy in the upright position), then can one subscribe to the aggravation but not the creation of a ptosis from such an injury.

Renal ptosis has never been seen in patients of good musculature and proper posture. Clinical Significance of the New Concept of the Pathogenesis

Essentially, the treatment of extravasation resolves itself into (1) multiple incisions of the infiltrated tissues and (2) diversion of the urinary stream.

All writers on this subject indicate that Colles' fascia is continuous anteriorly with the dartos layer of the scrotum and penis. This is a very important point. From a surgical standpoint, if extravasations passed only beneath the dartos, only superficial incisions would be necessary to drain them. However, if extravasations invaded the deeper structures and the tunica vaginalis testis, deeper incisions would be required. Campbell,[5a] who has had extensive experience with extravasation, has stressed the importance of widely and deeply incising the scrotal sac, to such an extent that the completion of the operation finds the testes and spermatic cords completely exposed, "swinging free," bare, and, later, retracted over the lower inguinal regions. Since it has been shown that extravasated fluid (anatomically or clinically) does not invade the deeper structures or the tunica vaginalis testis, such a radical procedure would seem to be unnecessary and detrimental.

In the minds of those[5a,6,7] who have advocated diversion of the urinary stream, besides multiple incisions, in the treatment of extravasation, the rationale is to prevent more urine from being squeezed out into the tissues. On the basis of this reasoning many surgeons have failed to divert the urinary stream when stricture or retention was absent. In fact, many prominent urologists[8,1,9] do not mention this procedure.

The omission of urinary diversion has led to an unwarranted and high mortality. Even those who practiced diversion could not reasonably explain this procedure in patients who were obviously voiding well and who presented no stricture.

A glance at Fig. 1 will reveal that all periurethral inflammations or lesions must first penetrate the very vascular bulb or part of the spongiosum to reach the superficial perineal pouch.

In this passage from the urethra to fascial space they invariably involve the vascular tree, thereby easily setting up a vascular thrombosis or thrombophlebitis. Anterograde or retrograde extension of this process is favored by the contractions of the bulbocavernosus and external sphincter muscles, which are brought into play with each act of voiding. This explains the paradox in which the condition of extravasation is aggravated in those patients who continue to void. Moreover, this concept of the pathogenesis explains the development of extravasation without stricture or obstruction, and also the urgent necessity for diversion of the urinary stream, regardless of whether or not the patient is voiding well. These muscles must be put at absolute rest in order to prevent them from squeezing the thrombosed bulb and thereby extending the process into the scrotal and penile vessels.

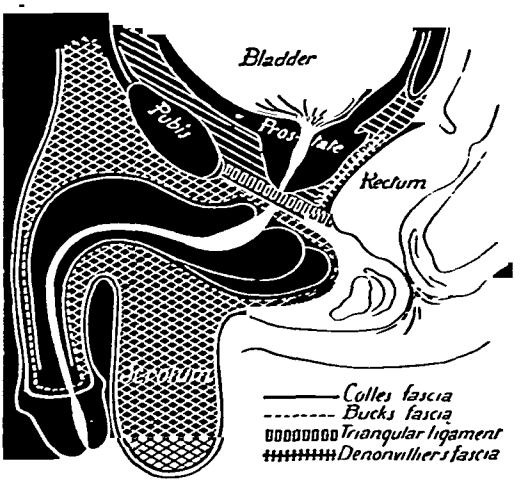

FIG. 1. Showing the fascial planes concerned in urinary extravasation as modified by Eisendrath and Rolnick after Wesson. Cross-hatched area represents infiltration below the urogenital diaphragm, whereas obliquely shaded area represents infiltration above the urogenital diaphragm.

This latter process accounts for the high incidence of toxicity and jaundice, the rapid appearance of the swelling of the penis and scrotum, and ultimate gangrene. On the other hand, if extravasated urine, blood, or an abscess occupy the superficial perineal pouch, it is easy to see how the pressure of the mass in the confined space would produce vascular obstruction of the scrotal vessels without actual thrombosis. This mechanism is seen in many periurethral abscesses. When the abscess is incised, the edema disappears because of the release of the pressure.

In this connection, I believe that the condition known as "idiopathic scrotal gangrene" is only another form of urinary extravasation or periurethral gangrene. All the reports[5a,10,11,12] on this mysterious condition use only one criterion in differentiating it from periurethral phlegmon; namely, the absence of stricture or obvious urethral lesion. In the light of the present concept, however, idiopathic scrotal gangrene is easily explained without stricture or obvious urethral lesion.

URINARY EXTRAVASATION (PERIURETHRAL PHLEGMON)

A New Concept of the Pathogenesis and the Treatment

EDWARD O. FINNEGAN, M.D., F.A.C.S., New York City

AS THE title indicates, there are two theories to explain the pathogenesis of urinary extravasation: (1) The older notion subscribed to the belief that urine was actually "squeezed" out into the tissues through a defect in the urethra. (2) The newer conception explains the picture on the basis of bacterial invasion, chiefly by anaerobes.

According to Hinman,[1] "Three types of urinary extravasation are commonly encountered: (1) Between the layers of Buck's[2] fascia from the pendulous or bulbous urethra. (2) Within the superficial perineal pouch below the urogenital diaphragm from the bulbomembranous urethra, or from the membranous urethra with rupture of the inferior layer of the triangular ligament. (3) Above the urogenital diaphragm, from the prostatic urethra if associated with rupture of the superior fascia of the urogenital diaphragm."

Of these three types the second is the commonest, and it is this one with which we are primarily concerned in this paper. Fig. 1 (modified after Wesson) demonstrates the various paths of urinary extravasation. Theoretically, if we presume a defect in the bulbomembranous urethra, the extravasated urine should extend beneath Colles' fascia into the perineum in front of the inferior fascia of the urogenital diaphragm. The attachments of Colles'[3] fascia are such that the fluid must extend forward beneath the dartos of the scrotum and penis, and then up over the abdomen beneath Scarpa's fascia. It may extend as high as the axilla. The urine cannot spread laterally or posteriorly because of the attachment of Colles' fascia to the pubic rami and the inferior layer of the urogenital diaphragm. Its spread on the thighs is limited by the fascia lata.

Pathogenesis

In a previous communication,[4] the anatomy, bacteriology, and pathogenesis of urinary extravasation were reviewed. The superficial perineal pouch of Colles' in cadavers was injected with radio-opaque colored fluid, the amounts and pressures were recorded, x-ray demonstrations were made as increments of fluid were injected, and, subsequently, the cadavers were dissected.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1942.

From the Surgical Service of Dr. Joseph B. Stenbuck at the Harlem Hospital, New York City.

The following conclusions were derived from these studies and experiments:

1. Anatomically, Colles' fascia is so disposed as to allow (theoretically) a progressive urinary infiltration of the perineum, scrotum, penis, groins, and anterior abdominal wall.
2. Injection experiments reveal that the clinical appearances can be simulated (with the exception of penile and abdominal involvement) by using pressures and amounts of fluid comparable to those expected on voiding.
3. Urine alone does not suffice to produce the clinical pictures.
4. Other factors are operative in the live subject—namely, (*a*) the presence of bacteria, (*b*) the tonicity, contractility, and elasticity of the tissues, and (*c*) an active circulation.
5. Various combinations of these factors, especially the virulence of the invading organisms, account for the varied clinical syndromes encountered.
6. The close proximity of the vascular tree to the urethra (bulb) permits the easy development of vascular thrombosis or pressure phenomena from encapsulated fluid or abscess.
7. Vascular thrombosis or infectious thrombophlebitis probably accounts for the frequency of rapid swelling of the genitalia and for the swift gangrene, severe toxemia, and jaundice.
8. Injection experiments demonstrate the ease with which the vascular tree is inadvertently entered.
9. Injection experiments conducted by x-ray and dissection together with clinical and autopsy records fail to show any case wherein the tunica vaginalis testis is involved in extravasation.

Factors Which Determine the Characteristics of Extravasation

1. Anatomic distribution of fascial planes.
2. Nature and location of urethral lesion.
3. Hydrodynamic pressure of extravasated fluid.
4. Vascular obstruction induced by pressure of perineal abscess, extravasated fluid, or blood.
5. Occurrence of vascular thrombosis or thrombophlebitis.
6. Elasticity, tonicity, and contractility of the tissues.
7. Nature of the invading organism.

2. It reduces to a minimum the trauma and manipulation of the urethra during the acute infection.

3. It frees the urethra from the presence of a foreign body and puts the muscles at rest.

4. It permits the tube to be more easily cared for and kept patent.

5. It is followed less often by perineal fistula.

Disadvantages of Perineal Urethrotomy

1. It requires unnecessary and harmful manipulation of the diseased urethra..

2. Thrombophlebitis, bacteriemia, pyelonephritis, undue urethral hemorrhage, or rupture of the urethra may be induced thereby.

3. It is technically difficult with impassable strictures without a guide.

4. It does not so effectually put the urethral muscles at rest.

5. It does not permit the tube to be so easily cared for postoperatively.

6. It is followed more frequently by perineal fistula.

Disadvantages of Catheter Drainage

1. It does not put the urethra at rest.

2. With so much infection already present, the catheter only aggravates the urethritis.

3. It is difficult to keep in place and patent.

4. It cannot be attached to the swollen and infiltrated penis.

5. It moves and loses the optimum site for drainage of the bladder, so that urine is either retained in the bladder or forcibly expelled alongside the catheter.

6. Its presence may induce prostatitis, seminal vesiculitis, epididymitis, or thrombophlebitis.

7. It results in the highest mortality.

Postoperative Care

1. Frequent wet dressings with warm solution of potassium permanganate.

2. Careful daily observation of wounds to note whether further infiltration develops, so that prompt revision, secondary incisions, or removal of sloughing tissue may be accomplished without delay.

3. Following control of extravasation, subsidence of fever, and stabilization of the patient's general condition, hot sitz baths, and gradual dilation of urethral strictures is begun. This is most easily conducted while suprapubic drainage is continued.

4. Periodic dilation and careful follow-up will prevent recurrence.

Prognosis

Three principal factors contribute to the high mortality in extravasation:

1. Severity of infection and toxemia.
2. Delayed treatment.
3. Improper surgical management.

Influence of Delayed Treatment

1. Of 13 survivors operated upon by suprapubic cystotomy or external urethrotomy, 9 were operated upon on the day of admission—whereas of 16 patients who died, only 6 were operated upon on the day of admission.

2. Of 7 patients that died after suprapubic cystotomy or perineal urethrotomy, only 2 were operated upon on the day of admission; the other 5 cases presented a delay of from one-half to five days before operation.

3. Of 7 patients that died following suprapubic cystotomy or perineal urethrotomy, the following number of days elapsed from onset to operation: 4, 7½, 7, 7, 7½, 11, and 12 days, respectively.

Conclusions

1. A newer concept of the pathogenesis is based on vascular involvement.

2. This concept not only explains the varied clinical syndromes encountered, but also yields a more rational basis for treatment.

3. Diversion of the urinary stream is essential even in the absence of urinary obstruction.

4. Injection experiments conducted by x-ray and dissection together with clinical and autopsy records failed to reveal any case wherein the tunica vaginalis testis was involved. Therefore, the avoidance of the deeper structures of the scrotum and especially the tunica vaginalis testis is stressed as a preventive of unnecessary mutilation.

5. Of 32 cases reviewed 16 died. Of 3 cases not operated upon all died. Of 11 cases subjected to suprapubic cystotomy 7 survived, and of 9 cases subjected to external urethrotomy 6 survived, while of the 9 cases operated upon without any diversion only 3 survived. Of the last 3 cases, 2 had only localized conditions resembling periurethral abscess. The other spontaneously ruptured his perineum, thereby adequately diverting the urinary stream and saving his life.

6. Of the last 7 consecutive cases treated in the latter part of 1938 and 1939, when the principles enunciated in this paper were emphasized, there were no deaths.

Causative Factors

At the Harlem Hospital in New York City, 32 cases were found in the ten-year period from 1930 to 1939 inclusive. Of these, 28 were colored patients. The high incidence of gonorrhea with its complications of periurethral abscess and stricture, neglect, and unwarranted and unskillful urethral instrumentation are the factors which combine to make extravasation more common in this hospital than in other institutions.

The most important factor in causation was stricture, which was found in 19 of our series of 32 cases. Nine patients had had urethral instrumentation, 2 patients suffered trauma from other causes than urethral instrumentation, and one case had a urethral stone. It is remarkable that 6 cases were voiding well and presented no genitourinary symptoms on admission to the hospital.

Both cases that had trauma not caused by instrumentation were compensation cases. They had fallen while at work and had struck the perineum. Partial rupture of the urethra due to this straddle injury was not promptly treated by diversion and led to subsequent extravasation.

History and Onset of Urinary Extravasation

1. Antecedent history of gonorrhea with frequency, dysuria, urgency, and gradually diminishing urinary stream may be elicited in rational patients.

2. All of these symptoms may be absent in insidious cases.

3. Careful questioning usually elicits a history of long-standing urethritis or stricture.

4. Superimposed upon either of these two conditions, one finds the situation recently altered by the advent of periurethral abscess or trauma incident to urethral instrumentation or straddle injury.

5. The onset of periurethral abscess may be very insidious, and not until it is associated with urinary retention, severe toxemia, or frank extravasation is the patient forced to go to the hospital.

Cardinal Symptoms

1. The chief symptoms are those of toxemia. Malaise, chills, fever, and prostration drive the patient to seek hospitalization.

2. Local signs and symptoms may be so minimal that valuable time is often lost before the true nature of the condition becomes evident.

3. With increasing toxemia and with the advent of urinary retention, hiccough, disorientation, delirium, stupor, and coma rapidly supervene. Jaundice is commonly present.

Local Signs of Extravasation

1. Initial tender, edematous swelling in perineum.

2. Rapid spread to scrotum, penis, groins, and abdominal wall.

3. Swelling is continuous, symmetric, pits on pressure, and yields slight tenderness.

4. In late cases there is enormous swelling of the scrotum and penis, with edema, bogginess, dusky redness, weeping, and desquamation of the superficial layers of the skin.

5. Finally, irregular black patches of skin and occasional frank crepitation make their appearance.

DIFFERENTIAL DIAGNOSIS

between

Urinary Extravasation	Periurethral Abscess
1. Rapid, progressive spread	1. Slow enlargement and tendency to confinement
2. Tendency toward symmetry	2. Tendency toward asymmetry
3. Poorly defined limits	3. Well-marked limits
4. Pits on pressure	4. Induration and tenseness
5. Minimal tenderness except in perineum	5. Well-marked tenderness
6. Exploratory puncture may reveal any type of fluid in perineum depending upon the cause	6. Exploratory puncture reveals pus
7. Marked toxicity with high incidence of jaundice	7. Mild toxicity

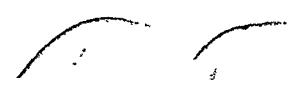
The two conditions may coexist, and frequently extravasation begins as a periurethral abscess.

Since both conditions require incision and drainage, the differential diagnosis is academic except for the urgency of diverting the urinary stream. Moreover, some periurethral abscesses, associated with urinary retention, are best treated by the addition of an external urethrotomy or suprapubic cystotomy.

Treatment

1. Operative intervention is essential and is always an emergency procedure. Spinal anesthesia gives the lowest mortality.

2. Besides multiple incisions of infiltrated tissues, diversion of the urinary stream is of paramount importance.



3. Diversion of the urinary stream is accomplished by one of three methods: (*a*) suprapubic cystotomy; (*b*) external urethrotomy; (*c*) indwelling urethral catheter (which is condemned).

4. Multiple incisions should be short and superficial. No necessity for exposing the testes. Unnecessary mutilation is thereby avoided.

5. The general condition requires strenuous measures: continuous intravenous infusions, transfusions, tetanus and anaerobic antitoxin, gas gangrene serum, and sulfonamides.

Advantages of Suprapubic Cystotomy

1. It most effectually drains the bladder.

EPIDIDYMITIS: ITS RELATIONSHIP TO TRAUMA AND COMPENSATION

Roy B. Henline, M.D., New York City, and William Yunck, M.D., Seattle, Washington*

THE development of epididymitis and its relationship to trauma, as defined by the New York State Workmen's Compensation Law, present a difficult problem to the urologist. The causes, both direct and indirect, and the pre-existing conditions necessary for the production of epididymitis are imperfectly understood. Only a few of the many patients suffering from prostatic or urinary infections develop an epididymitis, even though they may perform strenuous physical exercises. However, according to the Compensation Law, an illness is compensable even when it occurs or becomes aggravated because of a pre-existing condition. The opinions expressed by urologists in these cases are so divergent that a review of the relationship between epididymitis and trauma, with regard to our Compensation Law, seems justified. It is hoped that a clearer picture of the likely mode of infection, in the light of our present knowledge, may be presented, so that urologists will be closer to agreement.

Causation

There is little or no controversy regarding the compensability of a patient who has received a direct blow on the scrotum, resulting in the production of an epididymitis. For evidence of direct trauma, one should note immediate swelling in the scrotum, with severe pain and some degree of shock, which would be sufficient to prevent the man from continuing work. An effusion of serum or blood will be present in the tunica vaginalis, yet this may shortly be overshadowed by the epididymal lesion. The causal relationship between injury and disability in such a patient is apparent.

Any of the pyogenic bacteria may cause an epididymitis, but the staphylococcus, streptococcus, colon bacillus, gonococcus, and tubercle bacillus are the most frequent invaders. Although it has been shown that these bacteria cause the malady, their exact mode of entry to the epididymis is not completely understood. Every urologist has his own mental picture of how the epididymis becomes infected, but this point has not been conclusively proved and is still conjectural. The relationship, if any, of indirect trauma, such as straining, tugging, and strenuous lifting, to the production of an epididymitis, even by aggravating a pre-existing condition, must be considered.

Mode of Infection

Most cases of infection of the epididymis are produced by the migration of bacteria from the prostatic urethra, seminal vesicle, or urine along the vas deferens to the epididymis. Blood-borne epididymal infections are rare. However, other factors must conspire with prostatic, seminal vesicular, or urinary infection actually to produce epididymitis. Our knowledge of most of these accessory factors has been obtained from experience—the study of cause and effect—rather than from actual proof of the manner in which they conspire to produce the epididymitis.

In other words, with the same underlying infection not all patients will develop an epididymitis, even under similar circumstances. Experience has taught that, in the presence of genital or urinary infection, certain things may act as accessory agents in the production of an epididymitis and, hence, should be avoided. These may be briefly summarized as follows:

1. Metal instruments should not be passed into the urethra in the presence of an active urethral discharge, particularly if gonococci are present.
2. In acute prostatic infection the prostate may be *very carefully palpated*, but *not* massaged.
3. Dilatation of urethral strictures, in the presence of urinary infection, may result in an infection of the epididymis.
4. Sexual excitement and the use of alcohol predispose to the production of epididymitis in the presence of urinary infection.
5. *Excessive strain, lifting,* or *violent exercise* should be avoided since experience has taught that such strain predisposes to the setting up of epididymitis.

Although the exact relationship between direct or indirect trauma and infection is unknown, wisdom, based on experience, dictates that we accept the above as factors in the production of epididymitis until the mode of extension has been better demonstrated.

Occasionally a patient will develop an epididymitis, yet careful search will fail to disclose any evidence of prostatic, seminal vesicular, or

Discussion

Dr. Joseph D'Errico, *North Tonawanda, New York*—Dr. Finestone's paper has not enlightened me very much. In fact, feeling that we had finally come to a rational treatment for urinary extravasation, I am now confused, if anything.

First of all, let us distinguish between a periurethral abscess, per se, one with secondary extravasation, and traumatic extravasation without infection. Much is left unexplained when it is said that the orthodox picture of perineal trauma followed by swelling limited in extent by the triangular ligament, Buck's, Colles', and Scarpa's fascia with its familiar picture in its various stages is not extravasation. A voiding pressure of 80 mm. of mercury does not prove to me that an insulted vesical control mechanism cannot go well over that. How many of us have seen the 20-year-old man force the fluid level up in the irrigator under intense spasm while the scope was in place? A hypodermoclysis certainly does not need more than 80 mm. of mercury pressure to cause diffusion of the fluid.

The initial process is certainly extravasation. At what point the biochemical process of vessel thrombosis and tissue necrosis aids extension along the familiar planes is a matter of speculation. That these patients die of infection, anaerobic or aerobic, is not borne out by reliable culture studies with proper evaluation. Most of us certainly do not have infected bladders. Then why should we die of infection if this more or less sterile fluid extravasates?

The tremendous vascularity of the bulb and corpus cavernosum is familiar to all of us. We have seen patients who show a sharp rise in temperature on first voiding after prostatectomy, have positive blood cultures, yet recover in four or five days without any particular treatment. They literally voided bacteria into their blood streams.

To impress his underlings, Dr. H. H. Young gave a transfusion via the corpus cavernosum, thereby demonstrating the tremendous absorptive power of this particular area of the vascular system.

It is still extravasation to me, with death due to absorption of a by-product of a biochemical reaction of the urine, not to infection, unless it be purely contributory as a complication. To use a catheter in either diagnosis or treatment is almost unpardonable in all but the extremely rare instance.

Dr. George F. Hoch, *New York City*—Dr. Finestone deserves our plaudits for his clinical and experimental observations. His treatment of these cases should be standard.

NEW METHOD OF ADMINISTERING MORPHINE

Because of the critical shortage of tin, the U.S. Office of Civilian Defense has been unable to procure syrettes for administration of morphine by physicians of Emergency Medical Service. To meet this serious difficulty, a new device using glass and plastic has been developed.

This device consists of a small, scaled-glass ampule containing one-fourth grain or one-half grain of morphine in solution. This solution is under sufficient pressure to eject the entire contents. A piece of transparent plastic tubing encloses the neck of the ampule and connects it to the hub of the needle. The shaft of the needle is enclosed in a small glass tube, to which is attached a stylet. At the hub of the needle within the plastic tube is a small filter.

Following is the method of using the ampule:

1. The body of the ampule is grasped by the right hand.
2. The glass tube protecting the needle is withdrawn by a twisting and pulling movement of the fingers of the left hand.
3. With the needle pointing down and the body of the ampule vertical to the skin, the needle is inserted by jabbing it under the skin.
4. When the needle is in place, and with the ampule vertical to the skin, pressure is exerted with the thumb and two fingers on the plastic tubing to break the neck of the ampule. It is important that the ampule be held vertical to the skin, in order that morphine may not be lost by improper technic.
5. The pressure within the ampule ejects the contents. The filter prevents glass splinters from clogging the needle.
6. When the ampule is empty, the needle is withdrawn and the whole device is discarded.—*Rocky Mountain M. J.*

NEW LENS GRINDING INSTRUMENT

Production of precision lenses, the "glass eyes" of gunsights, binoculars, and other military instruments, has been greatly speeded by a diamond-impregnated grinding machine which automatically grinds curves or planes on glass. A wide range of curves can be ground with the device and from one to fifty lenses made in a single operation, depending on the size. . . . .—*Science News Letter*

EPIDIDYMITIS: ITS RELATIONSHIP TO TRAUMA AND COMPENSATION

Roy B. Henline, M.D., New York City, and William Yunck, M.D., Seattle, Washington*

THE development of epididymitis and its relationship to trauma, as defined by the New York State Workmen's Compensation Law, present a difficult problem to the urologist. The causes, both direct and indirect, and the pre-existing conditions necessary for the production of epididymitis are imperfectly understood. Only a few of the many patients suffering from prostatic or urinary infections develop an epididymitis, even though they may perform strenuous physical exercises. However, according to the Compensation Law, an illness is compensable even when it occurs or becomes aggravated because of a pre-existing condition. The opinions expressed by urologists in these cases are so divergent that a review of the relationship between epididymitis and trauma, with regard to our Compensation Law, seems justified. It is hoped that a clearer picture of the likely mode of infection, in the light of our present knowledge, may be presented, so that urologists will be closer to agreement.

Causation

There is little or no controversy regarding the compensability of a patient who has received a direct blow on the scrotum, resulting in the production of an epididymitis. For evidence of direct trauma, one should note immediate swelling in the scrotum, with severe pain and some degree of shock, which would be sufficient to prevent the man from continuing work. An effusion of serum or blood will be present in the tunica vaginalis, yet this may shortly be overshadowed by the epididymal lesion. The causal relationship between injury and disability in such a patient is apparent.

Any of the pyogenic bacteria may cause an epididymitis, but the staphylococcus, streptococcus, colon bacillus, gonococcus, and tubercle bacillus are the most frequent invaders. Although it has been shown that these bacteria cause the malady, their exact mode of entry to the epididymis is not completely understood. Every urologist has his own mental picture of how the epididymis becomes infected, but this point has not been conclusively proved and is still conjectural. The relationship, if any, of indirect trauma, such as straining, tugging, and strenuous lifting, to the production of an epididymitis, even by aggravating a pre-existing condition, must be considered.

Mode of Infection

Most cases of infection of the epididymis are produced by the migration of bacteria from the prostatic urethra, seminal vesicle, or urine along the vas deferens to the epididymis. Blood-borne epididymal infections are rare. However, other factors must conspire with prostatic, seminal vesicular, or urinary infection actually to produce epididymitis. Our knowledge of most of these accessory factors has been obtained from experience—the study of cause and effect—rather than from actual proof of the manner in which they conspire to produce the epididymitis.

In other words, with the same underlying infection not all patients will develop an epididymitis, even under similar circumstances. Experience has taught that, in the presence of genital or urinary infection, certain things may act as accessory agents in the production of an epididymitis and, hence, should be avoided. These may be briefly summarized as follows:

1. Metal instruments should not be passed into the urethra in the presence of an active urethral discharge, particularly if gonococci are present.
2. In acute prostatic infection the prostate may be *very carefully palpated*, but *not* massaged.

NEW LENS GRINDING INSTRUMENT

Production of precision lenses, the "glass eyes" of gunsights, binoculars, and other military instruments has been greatly speeded by a diamond-impregnated grinding machine which automatically grinds curves or planes on glass A wide range of curves can be ground with the device and from one to fifty lenses made in a single operation, depending on the size —*Science News Letter*

the presence of pus, and in doubtful cases a urine culture should be made. The prostate should be *gently* palpated for evidence of infection. At a later period, a smear of the prostatic fluid should be examined for the presence of pus.

If pus or infection is found in the urine, or in any quantity in the prostatic smear, one must then consider the possibility of this infection being a *pre-existing* focus of infection which has been *aggravated* by indirect trauma to produce the epididymitis. In the light of our past experience and the evidence pointing to the mode of infection of the epididymis, it is difficult to avoid the assumption that the presence of infection in the urine or the prostatic fluid is one of the factors in the production of epididymitis, and may be aggravated by sudden strain or lifting. Kennedy[7] points out that it has long been an accepted practice to prohibit strenuous physical activities in patients suffering from gonorrheal prostato-vesiculitis in an effort to prevent infection from extending down the vas deferens to the epididymis. The mode of extension to the epididymis appears to be the same when other organisms are present. He further states that if our assumption that excessive physical exercise predisposes to the extension of infection to the epididymis in venereal infections is correct, it is not unreasonable to assume that the same factors may produce an extension to the epididymis from other infections in the prostate or seminal vesicles. This conclusion is difficult to avoid in the light of our present knowledge and past experience.

However, this same conclusion does not apply to most accident insurance cases. Most accident policies do not cover an aggravation of a pre-existing condition, and direct trauma must be substantiated to warrant a claim on the insurance company. On the other hand, the wording of the Workmen's Compensation Law of New York makes an illness compensable if the condition was caused by an injury sustained by the patient while working, or if it resulted from a previous disease or infection which was aggravated by reason of his occupation. Since it is possible for a strain or lifting, in the presence of a urinary or prostato-vesicular infection, to be a factor in the production of an epididymitis, either the Compensation Law should be revised, or such cases should be considered compensable.

Summary

Past experience and available experimental evidence have taught us that a strain or excessive physical exercise should be avoided in the presence of infection in the urine, prostate, or seminal vesicles because of the possibility of producing an epididymitis. Until we have satisfactory evidence to controvert this theory, it seems logical to assume that a severe strain may be sufficient aggravation of a pre-existing urinary or prostato-vesicular infection to aid in the development of an epididymitis. When the history, presence of infection, and epididymitis develop in a logical sequence, the assumption of a relationship between the indirect trauma and the epididymitis would seem to be justified.

Discussion

Dr. George F. Hoch, *New York City*—The tendency of the day is revolutionary. It seems to me that Drs. Henline and Yunck have gone to an extreme in trying to establish a case against the carrier in regarding epididymitis to be compensable in all cases. The carriers for whom I have examined these cases are willing to settle the claims where I have indicated that trauma may have been a factor. There must be some place where urologists and the Compensation Board can meet in determining the compensability of each case. There is no argument against the causes given by these essayists, but as long as they are grouping sexual excitement and exercise as causes how are they going to settle the question? I have felt that where no infection exists as evidenced by urinalysis, smear, or rectal examination the case is compensable. This also brings up the question of a positive staphylococcus smear. In his work, Creevy has shown that about 30 per cent are pathogenic.

I would like to mention torsion of the cord as a traumatic lesion that has to be differentiated from epididymitis.

It is a far cry from Wesson and his plea against traumatic orchitis to this paper. When I tried to get one of the referees to formulate some rule on compensation in epididymitis, he said it would always be controversial. I believe he was made a referee for his sagacity as well as for his legal knowledge.

urinary infection. Prostatic enlargement and urethral stricture may also be absent, and the cause of the epididymitis is not ascertained. It has been suggested that in such cases the epididymitis is produced by chemical irritation from urine that has been forced down the vas deferens by a sudden strain.

Most urologists accept the theory that tuberculous involvement of the epididymis occurs, in most cases, from a primary urinary-tract infection in the kidney. In many instances, the primary focus in the kidney is not demonstrable clinically. Although its onset may be sudden and impossible to differentiate clinically from that of any other epididymitis, tuberculous epididymitis may begin insidiously, involving the upper pole of the epididymis more frequently and often producing a nodular or beady enlargement of the vas deferens.

The relationship of trauma to the production of tuberculous epididymitis is very difficult to decide. It may be possible for a sudden strain to force urine containing tubercle bacilli from a tuberculous kidney down the vas deferens. Tubercle bacilli from an infected kidney usually are found in the urine in showers, and at most times the urine contains no bacteria. Therefore, to make this theory tenable, such a sudden strain must occur at a time when a shower of bacteria has invaded the urine. However, according to Thomas,[1] tubercle bacilli are believed at times to be present in the vas deferens or epididymis without producing clinical epididymitis. At such times, even slight local trauma or strain may be sufficient to incite an inflammatory lesion in the epididymis caused by tubercle bacilli.

There is evidence for believing that, under certain conditions, urine may be forced down the vas deferens, carrying with it any bacteria present in the urine. O'Conor[2] cites two cases of prostatic hypertrophy in which silvol was injected into the patient's bladder after catheterization. Vasectomy, performed within twenty-four hours, showed the presence of silvol in the vas deferens as far down as the tail of the epididymis. Kreutzmann[3] found that infected bladder urine (as determined by culture) was necessary to produce an infection in the vas deferens, but that in a group of patients with prostatitis alone, excision of a portion of each vas failed to show the presence of infection. He concludes that viable organisms may be present in the vas without producing epididymitis, but that epididymitis occurs only in the presence of infected urine. He further suggests that, under certain conditions, reflux of urine into the vas deferens may occur. His studies showed that instrumentation doubled the possibility of producing epididymitis. Ewell[4] believes that urine may be forced into the vas deferens by a strain and states that indirect trauma (strain) may force infectious organisms in the urine, prostate, or seminal vesicle into the vas deferens. Pelouze[5] states that in 98 per cent of gonorrheal epididymitis the gonococcus reaches the epididymis by being forced down the vas deferens, and that this can largely be prevented by instructing patients to *avoid heavy exertion* and *sexual excitement* when there is any quantity of infected urine in the bladder. He believes that most nonspecific epididymitis is due to infected urine being forced down the vas deferens, frequently because of hyperplasia of the prostate, urethral stricture, a small urethral meatus, or prostatitis. A similar sequence of events may follow a severe strain, during which the external vesical sphincter is held so tightly closed as to act in the same manner as an urethral obstruction.

Cummings[6] states that 98 per cent of patients with chronic prostatic infection have one or more foci of infection elsewhere. Pelouze also believes that most cases of prostatitis are secondary to some more distant infective focus, and not due to transplantation of bacteria from the urethra. Such foci may be found in the teeth, tonsils, furuncles, or an intermittent pyelonephritis. The prostatic infection may occur silently, with the production of few or no symptoms, and may exist thus for years, the patient being entirely unaware of its presence. The urine may be sterile and contain no pus. In some instances—often owing to excessive use of alcohol or sexual excitement—this infection may become more acute and some of the pus may exude from the prostate and produce an infected urine. If a sudden strain should occur at this time, particularly with a filled bladder, some of this infection may be forced down the vas deferens with the urine. In other words, these smoldering and often asymptomatic prostatic infections are prone to exacerbations, at which time, in the presence of other factors which often include a *sudden strain*, an epididymitis may develop.

Causal Relationship in Workmen's Compensation

A urologist is often asked to decide whether a patient with an epididymitis should receive compensation according to our New York Workmen's Compensation Law. Many factors must be considered in rendering such a decision, particularly when a history of strain or indirect trauma is obtained. It would appear logical that some pain, tenderness, and swelling should occur in the scrotum at the time of the strain, yet all these findings may be more apparent several days later. A urine specimen should be examined at the earliest convenient moment for

TABLE 1.—Type of Reactions*

Reaction:	0	1	2	3	4
Number of Cases:	64	17	13	11	3
Percentage:	59	15	12	10	3

somewhat lowers the percentage of headaches. Let us study in greater detail the direct affect of bed rest upon spinal headache.

TABLE 2.—Effect of Bed Rest on Reactions*

To Bed After Spinal	Reaction According to Degree 0	1	2	3	4
Immediately	1		2	5	2
In 2 or 3 hours	10	5	4	3	
In 4 or 5 hours	15	5	3	1	1
In 6 hours	22	5	2	2	
In 8 hours	16	2	2		

Salient features of these tabulations are:

1. Of 10 men who went to bed immediately:
   (*a*) One had no headache, a percentage of 10.
   (*b*) Two had mild headaches.
   (*c*) Five had moderate headaches.
   (*d*) Two had severe headaches. Thus 7 men had moderate or severe headaches, a percentage of 70.
2. Of 20 men who went to bed eight hours later:
   (*a*) Sixteen had no reaction, a percentage of 80.
   (*b*) Two had slight reaction.
   (*c*) Two had mild reaction.
   (*d*) None had either moderate or severe headaches.
3. Of 38 men who went to bed after six hours, only 2 had severe or moderate headaches, a percentage of 5.

Two men had spinals elsewhere—one in the Army and one in a leading university clinic—as well as at our institution. Both went to bed immediately after the previous lumbar puncture and had severe reactions, whereas in our institution one went to bed after eight hours and had a slight reaction, and the other went to bed after four hours and had no reaction.

Thus we observe that bed rest is not only far from useful, but is apparently a harmful procedure in performing diagnostic spinal taps.

Our next step is to discuss causation from a new aspect. Dattner and Thomas[5] believe that neither the leakage theory nor the meningeal theory alone explains the reactions but that both factors may be present and that they both help to produce changes in the hydrodynamics of the central nervous system. They further believe that reflex responses of the vasomotor system have an important part in affecting such alterations. They further express the opinion that in some cases there may actually be an edema of the meninges or of the brain.

The retinal arteries, being the only visible access to intracranial vascular study, should be considered here. Fortunately, postpuncture changes in the ocular mechanism have been recorded by several workers. Levy *et al.*[6] reported 2 cases of papillary edema following lumbar puncture, the causation of which was attributed to the reactional hypertension that may follow the withdrawal of spinal fluid.

Guillain, Alajouanine, and La Grange[7] found congestion of the disk with dilatation of the veins and sometimes even edema in those persons who manifested headache, vomiting, or vertigo following lumbar puncture. They also consider these findings to be a reactional attack of intracranial hypertension, caused by a compensatory hypersecretion of the choroid plexus, subsequent to spinal fluid drainage.

Powell and Smith,[8] in a study to show the relationship between symptoms and fundus changes, found that out of 16 cases with changes in the optic disk 9 had nausea or headache.

In line with the works of these authors, we feel that intracranial hypertension is the cause of the headaches, and we will attempt to point out other factors that may influence the choroid plexus and thus influence intracranial tension.

Work done by Kulchar and King,[9] and also by Schube and Le Drew,[10] revealed enlightening observations that sodium amytal given by mouth before spinal tap cut the percentage of headaches by one-half, as compared with the group that received no medication or received codeine hypodermically.

Emotional reactions vary with sex and with race, as evidenced by the reports of other authors. Davenport[2] found that Puerto Ricans react most severely to spinal taps. Women have been found by various authors to be more reactive than men.

All our patients were institutional cases and were under our observation for at least one year. We were thereby afforded every opportunity to know intimately their emotional reactions and constitutional makeup. There are a number of patients who have many vague aches and pains, who are treated unsuccessfully, and who have a multiplicity of diagnoses. Alvarez[11] has classified these patients as "constitutional inadequates." The commonest symptoms are those of excessive fatigue, lack of energy, and lack of reserve strength. Other common complaints are aches and pains everywhere, nervousness,

* The following code applies to "Reaction" in Tables 1, 2, and 3

0. No headaches
1. Slight headache, usually lasting less than an hour, and appearing within several hours after tap
2. Mild headache.
3. Moderate headache
4. Severe headache, requiring hospitalization flat on back.

A STUDY OF THE HEADACHES FOLLOWING DIAGNOSTIC SPINAL TAPS

HARRY ADLER, M.D., Elmira, New York

DIAGNOSTIC spinal taps are becoming more and more essential in modern therapy. Unfortunately, this procedure is often followed by headache, a complication that has caused patients to refuse the spinal tap because of the pain or because the reaction may cause the individual to lose time from work. Our study and review of the literature were undertaken to bring some light on this subject.

Without question, it is very beneficial in therapy to understand causation. We, however, are far from knowing the cause of headaches in diagnostic spinal taps. At present, there are two outstanding theories—namely, the meningeal irritation theory and the leakage theory. These theories are inadequate in explaining headaches, and consequently, the prophylactic therapy is inadequate.

The tendency at present is to put the patient to bed after the spinal. The procedure varies in different clinics, and in some clinics bed rest is extended for twenty-four hours. The question is: is this prolonged bed rest essential, and, if not, is it harmful? According to Stokes,[1] even when every precaution is used some degree of reaction occurs in from 15 to 25 per cent of patients when they arise from bed on the day following puncture. Davenport[2] reported an incidence of 32.8 per cent moderate or severe reactions following lumbar punctures performed in Board of Health clinics in New York City. In our opinion, these figures are high, and an improvement should be undertaken.

We observed the shortcomings of the prevailing theory of causation and, as a result, recommend a change in the procedure of performing spinal taps. Many authors on the subject have felt that leakage of the fluid through the opening made by the needle accounted for spinal reactions. Later, study by other authors revealed that leakage is not the primary cause of spinal reactions. It is aptly concluded by Torbert[3] that, despite the wide acceptance of the theory of leakage of cerebrospinal fluid as the cause of the symptoms following lumbar puncture and the advancement of numerous other theories, nothing is known regarding the mechanism responsible for these symptoms.

It behooves us to reconsider the causative theories. If the leakage theory or the meningeal irritation theory were the answer, then a patient should have greater leakage in an upright position after the spinal and thus more severe headache. The same applies to the meningeal irritation theory.

When our theories of causation are incorrect and, as a result, we choose the wrong therapy, our results are difficult to understand. Davenport,[2] in his series, had the patient on the table for ten minutes, then instructed him to go home and go to bed. He remarked that it is surprising that jostling in the subways does not increase the reaction after puncture. Since tradition has it that postpuncture rest is a vital factor in minimizing headache, it should, then, be a source of surprise that the figures for reaction are low for patients who ride the subway immediately after puncture.

Torbert[3] reports that no significant reduction in the number of reactions following puncture is obtained by keeping the patients recumbent in a hospital for twenty-four hours following the operation. In his study, the patient was turned on his back and rested for two hours without a pillow. The usefulness of putting the patient to bed after a spinal is therefore highly doubtful.

Then the question arises, what results will we obtain if we allow patients to be up and about after spinals? The work of Blau[4] is illuminating in that his group had 48 reactions out of 421 cases, a percentage of 11. However, in a group that received no rest either at the clinic or at home there were 5 reactions out of 61 cases; a percentage of 8.

Our study consisted of 108 cases, and it was viewed from several aspects. We performed our spinals at 2:00 P.M., with the patient sitting erect, and did the tap as quickly as possible to avoid agitating the patient. We advised him emphatically to go to bed as late as possible; however, if the patient requested hospitalization, it was granted, and if the patient requested bed rest following the spinal, that was also granted. Since the men in our study are likely to take advantage of any opportunity to avoid work or to make known their complaints, our figures are more significant than they might be if they had been taken from a group of patients who must earn their own livelihood.

Of our 108 cases, 14 had moderate or severe reactions, a percentage of 13. We thus observe that encouragement to patients to stay erect after a spinal does not increase morbidity but

VITAMINS FOR GRAY HAIR

J. J. Eller, M.D., and Luis A. Diaz, M.D., New York City

RECENT reports contain some indications that certain cases of achromotrichia might be due to a vitamin deficiency. In 1938 several investigators[1,2] reported that rats reared on a diet deficient in certain constituents of the vitamin B complex developed a depigmentation of their fur, a condition which was promptly reversed by addition to the diet of the lacking factors. This "nutritional achromotrichia," as it has been called, attracted considerable attention. Shortly afterward several groups began to investigate the nature of the "anti-gray-hair factor."

One of the constituents of the vitamin B complex whose lack in the diet is capable of causing achromotrichia in animals was identified chemically as pantothenic acid.[3,4,5,6] Ansbacher[7] and Martin[8] a short time later reported that para-aminobenzoic acid had similar effects in animals, and Sieve,[9] who fed doses of 100 mg. daily to adults, reported that after about two months there was a darkening of the hair in all instances. It is still questionable whether para-aminobenzoic acid can be classified as a vitamin.

An editorial which appeared on January 24, 1942, in the *Journal of the American Medical Association* stated: "A diversity of opinion still prevails about the relation between diet and graying of hair in animals. Most investigators have been unable to verify Ansbacher's observation that para-aminobenzoic acid is related in any way with the phenomenon of graying hair in animals. The recent report of Unna, Richards, and Sampson[10] of the Merck Institute states that black rats which are fed a synthetic diet deficient in pantothenic acid become gray in about four to six weeks. Pantothenic acid at a level of 100 micrograms a day will prevent or cure this condition. Para-aminobenzoic acid in these experiments was entirely ineffective.

"Over ten years ago it was observed by a number of biochemists interested in nutritional anemia that black-haired rats became gray on a milk diet. When the anemia was developed on this diet, it was cured by administration of iron and copper, and the color of the hair likewise was restored to normal. Agnes Fay Morgan[1] and others showed in 1938 that a similar condition of gray hair could be produced in animals by a diet that did not contain all factors of the vitamin B complex. Thus came the conviction that vitamins may be concerned with this phenomenon. Even yet the experimental evidence is conflicting.

"Is para-aminobenzoic acid really concerned with the maintenance of normal dark hair color in man? If gray hair is darkened by administration of relatively large amounts of this substance, the effect may be due simply to the excretion into the hair of some paraphenylendiamine-like compound which acts like a dye.

"Further, in view of the paucity of information about the functions of para-aminobenzoic acid, it would be highly desirable to know something about the metabolic history of this chemical in the body before relatively large doses are administered to the patients over comparatively long periods of time. Finally, the evidence in behalf of some definite relationship between intake of vitamins and graying of hair is far more convincing for pantothenic acid than for para-aminobenzoic acid."

We have given para-aminobenzoic acid to 88 persons of different ages and sexes in various stages of achromotrichia. Included in this group were 20 inmates of a New York State penal institution. The patients were given 100mg. tablets 3 or 4 times daily over periods ranging from three to five months with no untoward effects. Each patient had blood pressure reading, urinalyses, and a general endocrine survey.

There were a small number that showed definite changes in the color of their hair. Each of these cases will be described separately.

Case Reports

Case 1.—Mr. G. was a 48-year-old inmate, whose hair had been gray for twenty-two years. On our first examination the hair all over the scalp was practically white. He had been under treatment for a cardiac condition and arthritis. He was given 100 mg. tablets of para-aminobenzoic acid three times daily. There was no change until after three months, at which time there was a definite appearance of black hair and at the end of five months this was so apparent that the appearance of the scalp was iron gray in color. In addition to our own observations, this observation coincided with that of the physician in charge of the institution (Dr. Banay).

Case 2.—Mr. S., an inmate (a lifer) aged 55, was apparently in good health except for an allergic dermatitis probably due to contact with rabbit fur. His hair was yellowish-white in color. After the ingestion of para-aminobenzoic acid in the above dosages for a period of ten weeks there appeared on the temple and occipital region a definite brownish-black discoloration of the hair. The patient stopped taking the para-aminobenzoic acid, and two months later the dark discoloration had practically dis-

faintness, dizziness, indigestion, poor appetite, loss of weight, regurgitation, a sensitive colon, palpitation, clammy hands, cardiac neuroses, slow recovery from any injury or illness, insomnia, "chronic fever," and "weak eyes."

We proceeded to classify all our cases according to the observations of Alvarez. We subdivided the patients into three groups—namely, normal, borderline, and constitutional inadequates. After we had all of the patients placed in their proper groups, we recorded the number and type of reaction of each group.

TABLE 3.—Reaction and Constitutional Makeup*

	Reaction					
	0	1	2	3	4	Total
Normal	48	14	9	5	1	77
Borderline	7	..	1	2	..	10
Constitutionally inadequate	9	3	4	4	2	22

1. Salient features of the normal group include:
   (*a*) Forty-eight out of 77 had no headache, a percentage of 62.
   (*b*) Six out of 77 had a moderate or severe headache, a percentage of 7.
2. Salient features of the constitutionally inadequate group were:
   (*a*) Nine out of 22 had no headache, a percentage of 41.
   (*b*) Six out of 22 had a moderate or severe headache, a percentage of 27.

We continued further study of the constitutionally inadequate group, and we made this additional observation: Of the 4 men who went to bed immediately, all 4 developed a moderate or severe headache.

Summary

It behooves us to reconsider the causation of spinal tap headaches and to suggest a change in the procedure of spinal taps. As we well know, blood pressure and metabolic readings, glandular functions, and the functioning of various and composite units of the sympathetic and parasympathetic nervous systems are markedly influenced by emotions; therefore, the choroid plexus may be influenced in the same fashion. As previously stated, edematous changes have been noted in the fundi of patients who have had headaches following spinal taps. Consequently, we believe that the headaches are due to an increased amount of fluid in the central nervous system. As previously reported by other writers, sedation given before spinal tap entails a lower percentage of post-tap headaches. In our own series, we find a definite correlation between constitutional inadequacy and headaches. We must recognize the fact that a patient lying flat on his back is bound to be very alert to any and all subjective sensations, and therefore we cannot deny that putting a patient to bed after a spinal to avoid a headache is apt to encourage introspection and thereby subject the patient to many troublesome thoughts and sensations. In light of this observation, it has been our procedure to perform the spinal tap with as little fanfare as possible, to encourage the patient to be up and about, and to regard this test as one similar to a routine Wassermann.

Conclusion

The sooner a patient goes to bed after a diagnostic spinal tap, the more apt he is to have a headache and the more likely it is to be a severe headache. The longer a patient is erect after spinal tap, the less apt he is to have a headache, and if one is present, it is likely to be mild.

We believe there are two factors that predominate as to the causative factors of spinal headaches—namely, constitutional makeup and *disturbed psychogenic influences.*

MODERN PILL BOX

A pill box which dispenses only one pill at a time has been recently patented. One pill at a time pops from a small opening in the molded, pocket-size container, the remainder being inaccessible and protected from dust and other contamination.—*Science News Letter*

LESIONS OF THE ANORECTAL REGION ASSOCIATED WITH SYMPTOMS OF PROSTATISM

JOSEPH A. LAZARUS, M.D., New York City

WHILE the term "prostatism" usually calls to mind an elderly man with an obstructing prostate, it is obvious that this syndrome may be, and frequently is, due to a variety of other conditions. Chief among these are the median bar and contracture of the vesical neck, which have given rise to the term "prostatisme sans prostate." This communication, however, will deal primarily with lesions in the lower bowel which have been found to be either directly responsible for the symptoms of prostatism, or to be so closely associated with the syndrome that one is unable to state with any degree of certainty just what role such lesions actually play in the clinical picture.

At the very outset it might be well to differentiate clearly between a case of prostatism associated with and directly due to the presence of an obstructing prostate gland and one associated with an enlarged prostate in which the gland plays no part whatsoever in the causation of symptoms. Diagnostic errors are frequently made, particularly by general surgeons and practitioners when they are presented with patients well within the prostatic age limit who complain of prostatism, and in the course of routine rectal examinations enlarged prostates are found. In such cases one is very apt to conclude without further substantiating evidence that the prostatism is due solely to the enlarged prostate. But in doing so one loses sight of the fact that an enlarged prostate is not necessarily an obstructing one.

Urologists are frequently confronted with patients who have had their prostates removed, but who return complaining of the same symptoms of prostatism which they had prior to operation. In a considerable percentage of such patients, careful cystoscopic and x-ray studies would undoubtedly have obviated such errors. There remains, however, a small group of cases which will elude the most painstaking and carefully performed urologic studies.

It might be well to digress for a moment in order to discuss briefly the mechanism underlying the symptom complex known as "prostatism." It seems to the writer that prostatism is essentially due to two factors: (1) actual mechanical narrowing of the vesical neck or of the prostatic urethra due to the prostate gland; and (2) superimposed spasm of the vesical neck, the detrusor muscle, or the trigone alone or in combination. Frequently, relief of one of these factors will result in the complete subsidence of all symptoms, depending upon the relative degree of obstruction produced by one or the other of these two operating influences. If, for example, the predominating factor is the prostate gland which, by virtue of its size or as a result of the fibrosis of the vesical outlet which it causes, is producing the occlusion, its extirpation by one means or another will result in alleviation of symptoms. This result ensues not solely because of the removal of the obstacle to the free flow of urine from the bladder, but by incidentally relieving the accompanying spasm of the muscles around the vesical neck. On the other hand, should the predominating factor be spasm, removal of the cause underlying the spasm may suffice to give relief. In this latter group of cases, it has been our experience that the enlarged prostate has served only as an incidental factor in the causation of symptoms.

Since it is intended to point out a few snares resulting from lesions in the lower bowel, which are ever present in the path of the urologist, it seems advisable to discuss this subject under two of its broader captions: (1) prostatism primarily due to the colonic lesion; and (2) lesions in the lower bowel which play only a coincidental role or no part at all in the clinical picture.

1. Bowel Lesions Giving Rise to Symptoms of Prostatism

(*a*) *Lesions Around Anus.*—Acutely thrombosed hemorrhoids, painful fissures in ano, and, occasionally, painful fistulae in ano, occurring in elderly men will frequently cause symptoms of vesical neck spasm which can be differentiated from prostatism due to hypertrophy only with difficulty. It is not unusual to find men with prostatism due to prostatic hypertrophy who present large and frequently thrombosed hemorrhoids. So that when one encounters a case in an elderly man in whom the hemorrhoidal lesion is primary, it is obvious that it will require diligent study to ascertain whether the prostate or the thrombosed hemorrhoids are responsible for the symptoms of prostatism. Proper attention directed to the anal lesions will relieve the prostatism only when such lesions are primary.

Case 1.—M. P., aged 47, was seen June 25, 1940, complaining of increased diurnal and nocturnal

appeared, and the hair had reassumed the yellowish-white color.

With the exception of a partially gray-haired negro who seemed to have an increase in the number of black hairs, there was no noticeable change in the color of the hair of the other 17 inmates under treatment.

In the other group of 68 patients, consisting of both men and women, there was only one case in which there was a definite change in the color of the hair. This was Mr. H. C., aged 51. He was in good general health. After two months' treatment there was a darkening of the hair all over the scalp, and on the top and temporal regions the hair actually became black. His moustache also darkened.

Three other patients having both gray hair and vitiligo showed no changes in either after four months' treatment.

In no patient in the entire group of 88 patients was there a complete change from white or gray to the normal, original color of the patient's hair.

Since the increase in pigmentation of the hair occurred in so few cases in the treated group, we are not certain that the para-aminobenzoic acid was the causative factor in the darkening of the hair.

Many of these patients were also given the vitamin B complex mixture that is described below, and those women near the menopausal age received estrogenic hormones in addition.

During the past two years, we have given to more than 200 patients a mixture consisting of an extract of the natural vitamin B complex* derived from high potency brewers' yeast flavored with sodium glutamate. These patients received no other vitamins or medication of any kind. The following is the formula: 10 Gm. (1 heaping teaspoonful) supply; 5.0 mg. thiamine (vitamin B_1); 2.4 mg. riboflavin (vitamin B_2); 22 mg. niacin; $^1/_6$ mg. pyridoxine (vitamin B_6); $^5/_3$ mg. pantothenic acid; $^5/_3$ Gm. protein; 2.4 Gm. carbohydrate; 0.05 Gm. fat; and 2.3 Gm. mineral (ash). While there were no spectacular results regarding changes in the gray-haired individuals, certain patients had a definite darkening of their hair. In others the hair became finer and more silky. In those individuals whose nails were brittle and frequently breaking off, there was a definite strengthening of the nails and loss of brittleness. The darkening of the hair and improvement in the nails may be attributed to an improvement in the general health of the patient rather than to any special vitamin. In discussing the gray-hair problem, many patients were of the opinion that their hair looked less gray when they were in better general health, especially in persons who were prematurely gray.

As pointed out by the *J.A.M.A.*: "Not all people whose hair has turned gray are necessarily suffering from a demonstrable vitamin deficiency. Before further experimental work is done on human beings it would be well to exhaust the possibilities of animal experimentation to ascertain the metabolic function of these substances that are present in yeast."[11]

We have certainly gained the impression from our observations and study of the available literature that the use of pantothenic acid or of para-aminobenzoic acid for achromotrichosis needs further investigation and corroboration before being expounded to the public as a "cure" for gray hair in humans.

AN EXPENSIVE HABIT

One of our readers sends us a fairly typical example of the overpayment to which patients are subject when physicians order proprietary drugs instead of writing out their own prescriptions.

The correspondent in question had received an advertisement giving the ingredients of a proprietary vitamin product retailing at $7.50 per hundred tablets. Struck by the high cost, he took the formula to his druggist for an estimate. The latter quoted a price of $4.50 per hundred—a saving of 40 per cent.

Most pharmacists will agree that the prescription of preparations under a proprietary name *increases* the costs of medication to the public. Moreover, it tends to reduce the pharmacist to the status of a mere middle man, discouraging the skill of an ancient and honorable profession.

For the *most part*, physicians order proprietary products instead of writing out their prescriptions from habit rather than conviction. It is a habit which should be discarded in view of the excessive costs it imposes upon the public.—*J. Med. Soc. County of N.Y.*

This case deals with a patient who presented enlargement of the prostate which in and by itself was fully capable of giving rise to all the symptoms of prostatism, and in addition an ulcerating carcinoma of the rectum with symptoms apparently only incidental to the prostatic syndrome.

Case 7.—H. Z., aged 68, was seen on July 10, 1941, after having been admitted to the hospital with acute urinary retention. He indicated that he had had symptoms of prostatism of several weeks' duration. The only symptom referable to the gastrointestinal tract was constipation, of which he had complained for several years.

Cystoscopy disclosed an enormously thickened and trabeculated bladder with marked hypertrophy of the median and both lateral lobes of the prostate.

Rectal examination disclosed a markedly enlarged, firm prostate, and nothing else. A two-stage suprapubic prostatectomy was performed, with the removal of an enormous prostate, diagnosed histologically as fibroadenoma. The postoperative convalescence was totally uneventful, and he was discharged from the hospital on August 20, 1941. About four and one-half months later he had an abdomino-perineal resection performed for carcinoma of the rectum.

This case illustrates a patient who was admitted as an emergency with acute retention of urine due to an enormous enlargement of the prostate gland, with no evidence whatsoever to indicate the presence of a malignant lesion of the bowel. It was only following the removal of the prostate that the presence of the rectal lesion was noted. It is obvious that the symptoms of prostatism in this patient were due solely to the hypertrophied prostate.

Case 8.—E. L., aged 58, seen on December 9, 1936, complained of prostatism of seven months' duration and also of constipation and loss of weight. Symptoms had begun seven months earlier, with hesitancy of the urinary stream. Four months before admission he began to have difficulty in voiding, diurnal and nocturnal frequency, dysuria, and perineal pains. Bowels had been constipated, and he had lost 20 pounds during the past seven months.

Cystoscopy revealed a marked intrusion of the middle lobe of the prostate into the vesical lumen, almost completely obliterating the view of the bladder cavity. The roof of the internal sphincter was acutely notched and there was moderate enlargement of the lateral lobes. By rectum the prostate felt moderately enlarged and firmly elastic. Situated directly above the prostate was a hard mass the size of an English walnut.

Sigmoidoscopy disclosed a flat firm papillomatous tumor involving the anterior and lateral walls of the rectum, 6 inches from the anus. Barium enema showed a defect in the region of the rectosigmoid.

So characteristic were the symptoms of prostatism and so confirmatory the urologic evidence of prostatic hypertrophy in this case, that it was only as a result of a carefully performed rectal examination that the carcinoma was palpated. It is our belief that the rectal lesion in this patient played no part in the symptom complex which he presented.

Case 9.—J. C. C., aged 69, seen on February 26, 1936, complained of repeated attacks of urinary retention, dysuria, diurnal and nocturnal urinary frequency, difficulty in starting stream, and constipation.

Symptoms had begun one year previously with difficulty in starting the stream. This became progressively worse until he suffered an attack of complete urinary retention, requiring catheterization. He had lost 15 pounds during the past five years. Although he was moderately constipated, he did not have attacks of diarrhea.

Cystoscopy revealed a slightly trabeculated bladder, with marked enlargement of the middle and both lateral lobes of the prostate. Residual urine measured 3 ounces. Rectal examination disclosed an enormously enlarged and elastic prostate.

A two-stage suprapubic prostatectomy was performed. On the seventh day after operation the patient began having frequent fluid bowel movements, which persisted until he was discharged from the hospital twenty-eight days after the first stage of the operation had been performed.

Eight days after his discharge from the hospital, rectal examination disclosed a large fungating carcinoma on the posterior wall of the rectum, which was reached with difficulty with the examining finger.

This case brings up another example of a coexisting carcinoma of the rectum in a man suffering from severe prostatism due to prostatic hypertrophy. At no time during the course of this man's preoperative urologic study or during the operative or postoperative periods was this lesion even suspected. Certainly its presence played no role in the causation of the prostatic syndrome. Our failure to recognize its presence prior to the removal of the prostate gland might have been due to 2 factors—namely, its high position in the rectum and to the fact that the enormous longitudinal enlargement of the gland made it impossible to reach it with the examining finger.

(*b*) *Symptoms Predominately Rectal:*

Case 10.—M. W., aged 76, seen October 16, 1940, complained of diarrhea, flatulence, blood in the stool, and prostatism of six months' duration. Eight years previously he had had a prostatectomy performed at another institution.

Rectal examination revealed a large cauliflower cancer involving the entire circumference of the rectum at a distance of 2.5 inches from the anus. The diagnosis was confirmed by proctoscopic examination and biopsy.

urinary frequency, dribbling, and difficulty in starting the stream, associated with belching and pyrosis. Fifteen years before he had had a gastrectomy performed for ulcer. Rectal examination disclosed internal hemorrhoids, fissure, and fistula in ano. Following hemorrhoidectomy along with the excision of the fissure and fistula, he made an uneventful recovery with complete disappearance of all urinary symptoms.

Case 2.—J. B., aged 61, seen September 23, 1930, complained of increased diurnal and nocturnal urinary frequency, dribbling, pain on defecation, and bleeding from the rectum. Proctoscopic examination disclosed a fissure in ano with hemorrhoids, for which surgery was performed. Following this he made an uneventful recovery, with complete disappearance of all urinary symptoms.

Cases 1 and 2 both illustrate prostatism due entirely to spasm of the muscles about the vesical neck which resulted from irritative lesions of the rectum and anus. Appropriate treatment directed to these causes led to complete relief of symptoms.

(*b*) *Lesions in Rectum and Colon.*—Cancers involving the lower portion of the rectum, and particularly the anterior wall of the rectum, frequently give rise to symptoms of prostatism, and occasionally lead to complete urinary retention.

Case 3.—S. R., aged 64, was admitted to the hospital on the night of April 28, 1941, with an attack of acute urinary retention. He stated that for the past few months he was troubled with diurnal and nocturnal urinary frequency. During this period he had lost 25 pounds in weight. Only after careful questioning was it ascertained that he had occasional bouts of diarrhea alternating with periods of constipation.

Physical examination disclosed a thin, cachectic, chronically ill patient who presented no outstanding signs. Blood pressure was 170/90. The prostate, as felt per rectum, did not appear particularly enlarged or hard.

Cystoscopy disclosed marked contracture of the vesical neck, with a well-defined median bar. The lateral lobes were not enlarged. On the anterior wall of the bladder near the vault there was a small area where the mucosa appeared reddened and edematous. This finding led us to believe that we might be dealing with a contact inflammation resulting from some intra-abdominal lesion lying adjacent to the bladder. It was fairly certain that the genitourinary findings did not fully explain the presenting clinical picture, particularly the general cachectic appearance of the patient, and the complete urinary retention.

Sigmoidoscopy disclosed a tumor involving the anterior wall of the rectum, situated 4.5 inches from the anus. Biopsy showed adenocarcinoma of the rectum.

Exploratory laparotomy performed May 13, 1941, revealed a large mass about the size of an orange involving the sigmoid flexure, upper rectum, one loop of small intestine, and the posterior vesical wall. A metastatic nodule was present in the right lobe of the liver. A loop colostomy was performed above the tumor. Following this, all urinary symptoms disappeared, indicating thereby that the urinary retention was primarily due to spasm rather than to mechanical obstruction of the vesical neck by the prostate gland.

Case 4.—S. McI., aged 59, was first seen July 14, 1930, complaining of increased diurnal and nocturnal urinary frequency, dribbling, difficulty in starting stream, and pyuria, of eight months' duration.

The physical examination was essentially negative. On rectal examination the prostate felt small and elastic.

Cystoscopy disclosed a thickened, trabeculated bladder with a well-defined median bar and contracture of the vesical neck. The lateral lobes of the prostate were not involved.

On July 29, 1930, the bar was excised with the Collings electrotome, and the patient was discharged from the hospital on August 1. He returned October 3, 1930, and stated that since leaving the hospital he had noticed rectal irritability which had become more pronounced during the preceding five days. Two months previously he had noted blood in the stool, which persisted for two days but did not recur. There was no diarrhea, constipation, or loss of weight. Digital rectal examination revealed a hard, annular carcinoma involving most of the anterior wall of the rectum, just barely palpable to the examining finger.

The symptoms of prostatism presented by this patient were undoubtedly due to spasm induced by the carcinoma of the rectum, which had been overlooked at the time of his first examination.

Case 5.—H. K., aged 58, was seen May 7, 1928, complaining of difficulty in urinating, frequency of urination, and dysuria. On rectal examination an ulcerating carcinoma was found involving the lower anterior wall of the rectum. The prostate was not enlarged.

2. Carcinoma of the Rectum Associated with Prostatic Hypertrophy

(*a*) *Symptoms Predominately Prostatic:*

Case 6.—M. H., aged 64, was first seen April 5, 1938, complaining of prostatism of three months' duration, constipation, pain on defecation, and blood-stained stools. The latter symptoms appeared to him to be only incidental to the prostatic syndrome.

Cystoscopy revealed a thickened and trabeculated bladder with marked hypertrophy of the median and both lateral lobes of the prostate.

Rectal examination disclosed not only marked enlargement of the prostate, but also an ulcerating carcinoma of the rectum.

The treatment in this case consisted of a two-stage suprapubic prostatectomy, followed by a Mummary resection of the rectum for carcinoma.

proctoscopic or sigmoidoscopic investigation. Should this fail to establish the presence of a tumor, it may be necessary to fluoroscope the colon with a barium enema.

It is even more important to carry out such collateral examinations upon men complaining of prostatism but presenting inconclusive evidence of prostatic obstruction following careful urologic study. In this group, especially among younger men, one should look with particular care for painful fissures in ano and small thrombosed hemorrhoids.

In patients with markedly enlarged and obstructing prostates, who give preoperative symptoms in any way suggestive of rectal irritability, and when preoperative studies have failed to disclose the presence of a rectal lesion, it is always advisable to repeat such studies within a reasonable period following the removal of the prostate.

The problem of proper handling of patients who present a combination of lesions involving the prostate and the terminal colon is one which depends upon a variety of factors. When the prostatic involvement is of secondary importance, appropriate treatment of the anorectal lesion will, in the vast majority of instances, suffice to relieve all symptoms of prostatism. When the prostate plays an equal role with the anorectal lesion in the production of symptoms, it has been our custom to direct attention first to the prostate, and later to the rectum. And finally, where the prostate is solely responsible for the symptoms of prostatism, and the anorectal lesion is an accompanying condition, unless there is the possibility of a threatening intestinal obstruction, we direct our attention first to the prostate, and later to the intestinal lesion. Should the intestinal lesion give rise to the more urgent and distressing symptoms, and particularly should there be any indication of an impending intestinal obstruction, it is better judgment to colostomize the patient before attending to the prostatic obstruction. It may, under certain circumstances, be necessary to introduce a temporary indwelling urethral catheter shortly after performing a colostomy, or to perform a suprapubic cystotomy if it is deemed inadvisable to delay the direct removal of the prostatic obstruction.

In regard to the type of prostate operation to be employed in this group of cases, it seems to us that wherever possible the transurethral resection is the method of choice, especially when renal function is not materially impaired. In uremic and suburemic states, suprapubic cystotomy is advisable regardless of whether or not the prostate is to be subsequently removed by enucleation or by the transurethral resection. It is obvious that in cases in which it is deemed prudent to perform a two-stage suprapubic prostatectomy, this procedure must take precedence over the extirpation of the rectal carcinoma.

Summary and Conclusions

Prostatism may be due to lesions in the anorectal region alone or in combination with obstructive hypertrophic prostates. When it results primarily from anorectal conditions, it is usually due to spasm of the vesical neck following irritation of the anterior rectal wall. Histories taken from prostatics must include careful interrogation regarding the bowel habits of these patients. In all prostatics carefully performed rectal examinations are imperative. Where symptoms point to the possibility of involvement of the rectum or anus, digital examination must be supplemented by proctoscopic, and, at times, x-ray studies of the colon. When symptoms suggesting rectal irritation are present, and when preoperative studies have failed to disclose any evidence of rectal pathology, it is essential that a careful rectal examination be made following the removal of the obstructing prostate. Appropriate treatment to an obstructing prostate should usually precede treatment for the anorectal pathology, unless intestinal symptoms strongly predominate. The procedure of choice, in dealing with the prostate in this type of case, is transurethral resection.

FISHING EQUIPMENT NEEDED BY NAVY

Hook, line, and sinker—and all the rest of your fishing equipment are needed to help save the lives of our fighting men. An appeal has gone out from the Medical and Surgical Relief Committee of America.

Mrs. Huttleson Rogers, executive chairman of the committee, urges that all fishermen, sporting goods dealers, and fishing clubs send her organization their spare or discarded fishing tackle. They are needed to help equip special emergency medical kits earmarked for the U.S. Coast Guard and the U.S. Navy.

A simple fishing outfit, for use in time of disaster, is now being included in the portable kit along with essential drugs and emergency surgical instruments. Already the lives of U.S. survivors of torpedoed boats have been saved by catching fish, which are not only valuable for food, but also contain water.

This illustrates a case of carcinoma of the rectum, in which the symptoms were primarily rectal in origin, and only secondarily gave rise to symptoms of prostatism.

Case 11.—E. S., aged 53, seen September 25, 1941, complained of irregular bowel movements and blood in the stools. During the preceding year he had noted increasing constipation, followed by bouts of diarrhea. Stools were frequently blood-stained. He had lost 20 pounds during the past two years. He also noted hesitancy of the urinary stream and increased diurnal and nocturnal urinary frequency.

Rectal examination revealed a large fungating carcinoma involving the anterior rectal wall, situated 3 inches from the anus. The diagnosis of carcinoma was confirmed by removing a section of the tumor for biopsy through the proctoscope.

This is another example of a patient presenting clear-cut symptoms of rectal carcinoma, along with symptoms of prostatism, the latter being definitely incidental and in no way due to the enlarged prostate.

Comment

Prostatism as a syndrome is most frequently due to interference with the vesical outlet by an obstructing prostate gland. There is, however, a small group of patients consisting of men in the prostatic age period who harbor lesions in the anorectal region of the colon among whom prostatism may be either the chief complaint or only a secondary syndrome. In this group the prostate may be pathologic or normal. For example, a man may present a history of prostatism, but on rectal and cystoscopic examination one may find no involvement of the bladder neck or prostatic urethra; or the changes may be so slight that an existing abnormality present in the prostate could not possibly account for the symptoms. Such an examination may reveal the presence of a painful fissure in ano, acutely thrombosed hemorrhoids, or a carcinoma involving the anterior wall of the rectum or lower colon. Each of these lesions, in itself is sufficient to cause symptoms of prostatism, owing to its tendency to initiate spasm of the vesical neck.

Then again, these same lesions of the rectum or anus may be present in men who actually do have some degree of prostatic hypertrophy. Yet, in these patients, careful cystoscopic studies fail to indicate that these hypertrophic glands exert sufficient occlusion of the vesical neck or prostatic urethra to initiate prostatism, indicating thereby that the prostatism is due solely to the irritating influence of the anorectal lesion and not to the inert prostate.

There is still another group of patients who present the prostatic syndrome, with both a lesion of the anus or rectum and an enlarged prostate which exerts an appreciable degree of obstruction to the bladder outlet. In this group the symptoms of prostatism may be entirely or only partially due to the enlarged prostate. When they are entirely due to the prostate, the accompanying rectal lesion is inert as a symptom producer. However, when symptoms are only partially due to the influence of the prostate, the anorectal lesion may accentuate them by virtue of its irritative effect upon the vesical neck.

Finally, we see patients who present clear-cut syndromes which point to involvement of the lower bowel segment, but who, on careful questioning, will also present symptoms of prostatism. On examining such patients both rectally and cystoscopically, one may find the prostate either enlarged or perfectly normal.

It has been our lot to learn through hard and often bitter experience that on taking a history of a prostatic one should question carefully and thoroughly about the bowel habits of the patient. It is particularly important to note whether or not there has occurred any change in the character of the stools, the number of stools per day, and the presence or absence of blood in the stools within the past six or eight months. Careful interrogation should also be carried out relative to any recent weight loss. The not-too-frequent association of anorectal lesions, particularly carcinoma of the rectum, with hypertrophic prostates makes it incumbent upon the urologist to be especially alert to the possible existence of this combination, and to attempt to eliminate the possibility of such a lesion before instituting treatment for the prostate.

We have often found it possible to detect lesions situated high up in the rectum by a properly carried out digital rectal examination. The patient, lying in supine position, is asked to flex his thighs upon the abdomen and then to flex the knees. He is then asked to draw his flexed knees, with his hands, up toward the chin. The examining finger is carefully introduced into the rectum as far as it will go, and the patient is then asked to strain as in moving the bowels. In this way it is often possible, by carefully sweeping the examining finger all around the circumference of the rectal wall, to pick up a tumor which might otherwise have eluded the examiner. However, in cases in which the prostate is particularly enlarged posteriorly, it is often impossible to reach far enough above its upper border to examine fully this segment of bowel for tumor. To eliminate the risk of overlooking such a lesion, particularly when symptoms point to the possibility of its existence, it is essential to carry out appropriate

year later she noticed recurrence, and five years later she had an operation for a large toxic intrathoracic goiter. She died on the seventh day with symptoms of storm.

9. Man, aged 67. Large intrathoracic goiter. Thyrocardiac. Pulse 164, very irregular. After three months, his pulse was 120, and still irregular, but he was walking between 4 and 5 miles. He died after four years from heart disease.

10. Woman, aged 61. Large nodular goiter. Thyrocardiac. Pulse 120; heart enlarged; valvular disease. After three months she felt very well, her pulse was 92, heart less enlarged. She was in good health for amost ten years, then was sick for two months and died. The exact cause was unknown.

On analyzing these 10 subsequent deaths we find that thyroidectomy apparently improved or prolonged life in five, had no effect in two, a doubtful effect in two, and seemed to make the patient worse in one.

The average age of these 11 patients five years after their operation would have been 43.8 years. At this age, according to *Insurance Tables of Life Expectancy*, 1.077 in every 100 are expected to die annually, or 10.77 in ten years. Our actual number was 11, or just about the average. But it must be remembered that we started out with 100 sick patients, probably none of them insurable. Some of those operated upon—for example, the one with cancer, or some of the thyrocardiacs—would have died without operation, and a number of them would have died sooner without operation. Therefore, we are safe in concluding that life expectancy is increased by thyroidectomy in proper cases.

The influence of the thyroid on blood pressure is variously estimated. Many physicians believe that goiter, both toxic and nontoxic, causes hypertension and that removal of the goiter, therefore, cures it. This we did not find to be true in our series.

We did find that after three months the pressure went down slightly in 30 out of 52 cases, but after ten years it had gone up in 80 per cent of the cases.

There were 14 patients alive after ten years whose systolic pressure before operation had been over 150 and whom we may arbitrarily consider as suffering from hypertension. The average systolic pressure of these cases before operation was 157.2; after three months it was 149.5, and after ten years, 175.4. Of the patients who died, one had a pressure of 198 before operation, 220 after four years, and died after eight years of nephritis; a second had a pressure of 196 before and 180 after three months; a third had 170 before and died after two months; and a fourth, 150 before, with 152 after one year.

We would conclude from these figures, therefore, that thyroidectomy has little effect on blood pressure, except a slight temporary improvement, and is no cure for hypertension. And the corollary to that would be that hypertension is not caused, but may be somewhat increased, by hyperthyroidism.

These findings agree with Bisgard, who recently made a similar study.[2]

Thyroidectomy had a very definite effect on the heartrate. Of the 70 cases examined, the average rate before operation was 94.5, while after ten years it was 79.5. There were 23 cases that had a rate of 100 or over before operation. Of these only 4 continued to have a rate over 100 after ten years.

Of the 60 patients who were asked whether there was a recurrence or persistence of the fast pulse or nervousness or both that they had had before operation, 53 answered no and 7 yes.

Of the 14 patients who had definite organic heart disease before their thyroidectomy, 11 were clinically cured, and 3 improved after ten years. This does not include those who died.

In the matter of weight, 57 weighed more, 7 weighed less, and 2 weighed the same after ten years. But there was no excessive gain in any case, nor did any patient who was thin before operation become definitely obese.

Of 32 married women under 40 in this group, 8 became pregnant. Two had 3 children, 3 had 2 children, and 3 had one child each. One of the children in the first group was very obese, of the Fröhlich syndrome type, but the child's two sisters were normal and their mother showed no signs of hypothyroidism.

In estimating recurrences of goiter, we counted all palpable enlargements of the thyroid residue, the majority of which were apparently not growing or causing symptoms. In 70 cases, there were 7 recurrences. A few of them required reoperation, one of them resulting in death, as reported among the subsequent deaths.

Examination of the scar in 70 cases showed that 62 were perfectly satisfactory, 4 were slightly thickened or widened, one had a depression from a temporary tracheotomy tube, 2 showed adherence of part of the scar to deeper parts, and one had a severe x-ray burn from treatment before operation. In no case did a patient accept the offer of a minor plastic operation to improve the scar.

All the patients examined were asked the question, "Do you think that your operation was successful?" Sixty-eight replied that they were satisfied and only 2 that they were not, in spite of the 7 recurrences.

Then each was questioned about the presence of the most common hyperthyroid or hypothyroid symptoms at the time of examination Thirty said no symptoms were then present

THYROIDECTOMIZED PATIENTS AFTER TEN YEARS

Analysis of 100 Consecutive Cases

ALFRED H. NOEHREN, M.D., Buffalo

REMOVAL of most of an organ, like the thyroid gland, that has a very definite effect on the metabolism and other functions of the body is bound to cause important changes in the well-being of that body. It is important that we know before undertaking such an operation whether these changes are beneficial or not, whether they are temporary or permanent, and what the final result will be. As Hertzler says, "Statistics can be of value only when the entire subsequent life span of the individual is taken into account."[1]

In order to determine what the effect of a thyroidectomy is on the subsequent life of the patient, we made an exhaustive study of the fate of 100 consecutive thyroidectomized patients operated upon before June 1, 1932. We were successful in obtaining reliable information about 87 of them and in personally examining 78½ per cent of the survivors. This is shown in Table 1.

TABLE 1.—100 CONSECUTIVE THYROIDECTOMIZED PATIENTS OPERATED UPON TEN YEARS AGO

Operative death	1
.....	10
.....	70
.....	7
.....	12
	100

The 88 cases of which we have information were classified at the time of operation as follows:

Nontoxic diffuse goiter	2
Toxic diffuse goiter	20
Nontoxic nodular goiter	47
Toxic nodular goiter	19
	88

We did not wish this to be a purely statistical study or to be guided merely by laboratory tests. Among other things we tried to find the answer to two questions: (1) what happens to these patients clinically, and (2) are some of our accepted concepts about thyroid patients borne out by experience?

In our study, we not only made a physical examination of each patient, but also questioned her about her own reactions to the operation. We do not consider any operation completely successful unless the patient feels that it was successful.

Before giving the results in our surviving patients, we will first briefly analyze the cases of those who have died during the ten years.

The operative death was in a woman 48 years old, who had a toxic diffuse goiter. Her pulse rate was 148 to 160 and she had a basal metabolic rate of plus 51. She was prepared in the hospital for nine days. Her pulse dropped to 112, and she started to gain weight and was calm. She died on the fourth postoperative day from a thyroid storm. The specimen showed marked epithelial hyperplasia. We believe that her toxicity was underestimated and that added experience would prevent such an occurrence today, for we have had no definite thyroid storm in a long time.

Subsequent deaths:

1. Woman, aged 28. Nontoxic cyst, the size of a coconut. The patient was in perfect health when seen three months postoperatively. She died two years later; cause unknown.

2. Woman, aged 54. Toxic nodule, the size of an orange. She died nine years later of carcinoma of the stomach. She was in good health until six weeks before death.

3. Woman, aged 55. Thyrocardiac. Blood pressure, 198/110. Three months later her blood pressure was 226/150. She died after eight years of cardiorenal disease.

4. Woman, aged 45. Slightly toxic nodule the size of an orange. Malignancy was not suspected, although a 20-year-old goiter suddenly started to grow five months previous to operation. Three months later there was extensive recurrence and dyspnea. The patient died after eight months of recurrences.

5. Woman, aged 46. Toxic diffuse goiter; pulse 126; basal metabolism, plus 68. After three months, her pulse was 124, and her basal metabolism was plus 25. Hysterectomy for fibroid was performed ten months later. Death resulted from embolus.

6. Man, aged 43. Toxic nodular goiter. Thyrocardiac. Basal metabolism, plus 51. Pulse became irregular on the second day after operation and remained so. One year later it was still irregular, with a basal metabolism of plus 19. He died suddenly five years later.

7. Woman, aged 51. Toxic diffuse goiter. Pulse 120; basal metabolism, plus 55. Pulse occasionally irregular. After operation, there were two attacks of fibrillation which were controlled with quinidine. The patient went home on the sixth day but died suddenly after two months.

8. Woman, aged 54. Large nontoxic nodule. There was no recurrence after three months. One

Case Report

INSULIN RESISTANCE

Report of Clinical and Experimental Findings in an Insulin-Refractory Case of Diabetes Mellitus

HERBERT SCHREIER, M.D., New York City

MARTIN and Martin[1] have presented a critical survey of the literature on insulin resistance. Out of 26 cases collected, 12 patients died despite therapy. They reported their own case of a previously mild diabetic, who presented allergic reactions to insulin and thereafter became insulin-resistant and died in diabetic acidosis despite enormous doses of insulin.

We are presenting a similar case, which we observed to be insulin-refractory from March, 1942, to July 27, 1942.

Case Report

Mrs. R. G., a woman 58 years old, was first seen in the Diabetic Clinic of Gouverneur Hospital on May 10, 1940. A neighborhood pharmacist had had her urine examined, and it was found to contain sugar. The chief complaints were: polyuria, polydipsia, and general weakness. Her maximum weight was 210 pounds, with a loss of 30 pounds in the past year.

Past History.—Hysterectomy, bilateral oophorectomy, an[illegible] performed when she was [illegible] nopause. There was no [illegible]s. Physical examination showed her to be obese, without any apparent endocrine stigmata. The heart sounds were of good quality, without murmurs, R.S.R. The lungs were clear. The blood pressure was 130/80.

Laboratory Data.—Fasting blood sugar was 250 mg. The urine showed 2 per cent glucose in 2,000 cc. of a twenty-four-hour specimen, with no acetone.

The patient did not return to the clinic until March, 1942, and from 1940 to 1942 she had had no medical attention. Her son admitted that she considered herself well and did not want to subject herself to medical management. She was unusually hungry at all times, consuming enormous amounts of food although she continued to lose weight. She had lost over 40 pounds in the course of these two years, a total weight loss of 70 pounds. On examination the urine showed a 4 plus reaction for sugar and a 4 plus reaction for acetone. She was hospitalized at Gouvenreur Hospital on March 7, 1942, on Dr. S. N. Weber's service, and was put on insulin for the first time. On the second day of hospitalization, the house physician noted an urticarial rash over the patient's body. A dose of 0.5 cc. of adrenalin was given, with immediate disappearance of the urticaria. The rash recurred in milder form, but disappeared again after a few days. The patient was discharged March 18, 1942, acetone-free but glycosuric. By this time she was more cooperative and appeared at the clinic at regular weekly intervals. Glycosuria in large amounts persisted despite high doses of protamine zinc insulin (70 units) and variable amounts of regular insulin (up to 50 units).

On April 10, she was readmitted to Gouverneur Hospital because of recurrence of ketonuria. On this second admission, she had 4 plus sugar and 4 plus acetone, and also showed a marked unilateral conjunctivitis, thought to be of allergic origin. The patient continued to spill sugar and acetone for about ten days despite routine management directed toward the establishment of electrolyte balance, large doses of insulin, and glucose. She remained conscious and at no time lapsed into coma. When over 400 units of insulin were given daily and large amounts—over 100 Gm.—of sugar were excreted in the urine, we undertook the study of: (1) sugar tolerance, (2) sugar and insulin tolerance, and (3) insulin tolerance.

(In the past three years, in cooperation with Dr. Fabrykant, we have subjected difficult diabetics to these tests in order to study: (1) sugar tolerance; (2) the effect of insulin on the blood sugars, (3) the effect of insulin on the amount of glycosuria, and (4) the detection of persistent glycosuria with normal blood sugar levels, which we found in some diabetics.)

The results of these tests in the patient were as follows:

Time	100 Gm. Glucose	100 Gm. Glucose Plus 50 Units of Insulin	Insulin Only, 50 Units of Regular Insulin
Fasting	344	310	344
½ hour	377	341	370
1 hour	380	345	390
2 hours	350	426	360
3 hours	339	417	360

The amounts of glycosuria during these tests remained within the same range, with insulin having no effect on either the blood sugar or the amount of sugar excreted in the urine.

By this time, we concluded that we were dealing with a case of insulin resistance of unknown cause. The patient continued to take large doses of insulin and continued to spill sugar and acetone. The acetone disappeared while the patient had six feedings with 50 units of regular insulin at each feeding; yet she continued to excrete large amounts of sugar in the urine. On May 21, she was discharged from the hospital with a diet of carbohydrate, 200 Gm.; of fat, 80 Gm.; of protein, 80 Gm.; with 60 units of insulin before each meal. She was closely watched at the clinic, and traces to 4 plus acetone began to appear in her urine. At this time a research bed was reserved at the New York Hospital.

Physical Examination.—On admission to the New York Hospital the patient was found to be moderately well developed, poorly nourished, showing obvious signs of great and recent weight loss. Intraocular tension was apparently normal, fundi were normal, and the tongue moist, showing no evidence of

Read at the Clinical and Pathological Conference at Gouverneur Hospital, New York City, November 19, 1942.

Chief of the Diabetic Clinic and assistant visiting physician, Gouverneur Hospital.

For the remaining 40, Table 2 shows the frequency of these symptoms.

Subjective heat	9	Swelling of face	1
Increased sweating	9	Drowsiness	1
Dyspnea	8	Falling of hair	1
Feeling of cold	6		

Previous exophthalmos had disappeared in 2, become less in 5, and become worse in none. Although we know that some cases of exophthalmos get worse after thyroidectomy, there were none in this series that did.

There was no definite case of myxedema in all the 70 patients examined.

The final question asked was, "How are you feeling today?'

The answers were as follows:

Very well	22
Good	42
Fair	4
Poor	2

Of the 64 patients who felt well or very well, 56 attributed their good health to their thyroidectomy; 2 were uncertain, one of these giving a subsequent x-ray treatment equal credit; 4 gave partial credit to the operation, and 2 none at all.

Analysis of the 4 patients who felt only fair showed that in 2 the poor health was due to recurrences. One of these patients has since been reoperated upon and now feels very well. The third patient is the only one in all our experience with serious permanent hypoparathyroid symptoms. She is still subject to spasms, which make her breathing difficult at times. Her Chvostek and Trousseau signs are positive, but there are no corneal symptoms. The fourth patient said that she "was a mess" before the operation and that while she is not in perfect health yet, she is much better than she was before.

Of the 2 who said their health is poor, one is suffering from gallstones and the other has had subsequent severe spinal complications, neither of which has any apparent relation to the thyroidectomy.

Conclusions

1. Lives are prolonged by thyroidectomy.
2. Thyroidectomy restores goiter patients to health.
3. Goiter increases hypertension, but does not cause it.
4. Thyroidectomy causes temporary improvement in hypertension in goiter patients, but does not cure it.
5. Cardiovascular cases that are caused or intensified by goiter—so-called thyrocardiacs—are definitely cured or improved by thyroidectomy.
6. Thyroidectomy has a tendency to increase weight to a moderate degree.
7. Thyroidectomy does not interfere with pregnancy.
8. Some recurrence of goiter after subtotal thyroidectomy may be expected in a little less than 10 per cent of cases.
9. From a cosmetic standpoint, the scar resulting from a thyroidectomy is of negligible importance.
10. Patients consider their thyroidectomy successful in over 97 per cent of cases.
11. Of the many symptoms of hyper- or hypothyroidism before operation surprisingly few are present ten years after the thyroidectomy.
12. Of 70 cases examined ten years after thyroidectomy, 64 are feeling well or very well today, and of the remaining 6 only 3 blame the thyroid or the operation for their ill health.
13. Of the 64 patients who are feeling well, 57 credit the operation with their well-being, 4 give it part of the credit, 2 are uncertain, and only one gives no credit to the operation.
14. Until better and more specific treatment for diseases of the thyroid gland is discovered, subtotal thyroidectomy in proper cases is amply justified by its ten-year results.

$1,000 BACTERIOLOGY PRIZE

The $1,000 prize and gold medal given annually by the Society of American Bacteriologists to an American bacteriologist under 36 years of age who has made an outstanding contribution to knowledge of the subject during the year were awarded to Dr. Harlan G. Wood, research assistant professor of bacteriology at Iowa State College.

Work tending to show that carbon dioxide acts as a vitamin-like substance necessary in the life of plants and animals won the award for Dr. Wood.

The award is presented at the annual meeting of the Society of American Bacteriologists, but as this was canceled this year, the award was presented to Dr. Wood at a joint meeting at Iowa State College of local chapters of the Society and of Sigma Xi.—*Science News Letter*

Case Report

INSULIN RESISTANCE

Report of Clinical and Experimental Findings in an Insulin-Refractory Case of Diabetes Mellitus

HERBERT SCHREIER, M.D., New York City

MARTIN and Martin[1] have presented a critical survey of the literature on insulin resistance. Out of 26 cases collected, 12 patients died despite therapy. They reported their own case of a previously mild diabetic, who presented allergic reactions to insulin and thereafter became insulin-resistant and died in diabetic acidosis despite enormous doses of insulin.

We are presenting a similar case, which we observed to be insulin-refractory from March, 1942, to July 27, 1942.

Case Report

Mrs. R. G., a woman 58 years old, was first seen in the Diabetic Clinic of Gouverneur Hospital on May 10, 1940. A neighborhood pharmacist had had her urine examined, and it was found to contain sugar. The chief complaints were: polyuria, polydipsia, and general weakness. Her maximum weight was 210 pounds, with a loss of 30 pounds in the past year.

Past History.—Hysterectomy, bilateral oophorectomy, and salpingectomy had been performed when she was 38, followed by surgical menopause. There was no family history of diabetes. Physical examination showed her to be obese, without any apparent endocrine stigmata. The heart sounds were of good quality, without murmurs, R.S.R. The lungs were clear. The blood pressure was 130/80.

Laboratory Data.—Fasting blood sugar was 250 mg. The urine showed 2 per cent glucose in 2,000 cc. of a twenty-four-hour specimen, with no acetone.

The patient did not return to the clinic until March, 1942, and from 1940 to 1942 she had had no medical attention. Her son admitted that she considered herself well and did not want to subject herself to medical management. She was unusually hungry at all times, consuming enormous amounts of food although she continued to lose weight. She had lost over 40 pounds in the course of these two years, a total weight loss of 70 pounds. On examination the urine showed a 4 plus reaction for sugar and a 4 plus reaction for acetone. She was hospitalized at Gouvenreur Hospital on March 7, 1942, on Dr. S. N. Weber's service, and was put on insulin for the first time. On the second day of hospitalization, the house physician noted an urticarial rash over the patient's body. A dose of 0.5 cc. of adrenalin was given, with immediate disappearance of the urticaria. The rash recurred in milder form, but disappeared again after a few days. The patient was discharged March 18, 1942, acetone-free but glycosuric. By this time she was more cooperative and appeared at the clinic at regular weekly intervals. Glycosuria in large amounts persisted despite high doses of protamine zinc insulin (70 units) and variable amounts of regular insulin (up to 50 units).

On April 10, she was readmitted to Gouverneur Hospital because of recurrence of ketonuria. On this second admission, she had 4 plus sugar and 4 plus acetone, and also showed a marked unilateral conjunctivitis, thought to be of allergic origin. The patient continued to spill sugar and acetone for about ten days despite routine management directed toward the establishment of electrolyte balance, large doses of insulin, and glucose. She remained conscious and at no time lapsed into coma. When over 400 units of insulin were given daily and large amounts—over 100 Gm.—of sugar were excreted in the urine, we undertook the study of: (1) sugar tolerance, (2) sugar and insulin tolerance, and (3) insulin tolerance.

(In the past three years, in cooperation with Dr. Fabrykant, we have subjected difficult diabetics to these tests in order to study: (1) sugar tolerance; (2) the effect of insulin on the blood sugars, (3) the effect of insulin on the amount of glycosuria, and (4) the detection of persistent glycosuria with normal blood sugar levels, which we found in some diabetics.)

The results of these tests in the patient were as follows:

Time	100 Gm. Glucose	100 Gm. Glucose Plus 50 Units of Insulin	Insulin Only, 50 Units of Regular Insulin
Fasting	344	310	344
½ hour	377	341	370
1 hour	380	345	390
2 hours	350	426	360
3 hours	339	417	360

The amounts of glycosuria during these tests remained within the same range, with insulin having no effect on either the blood sugar or the amount of sugar excreted in the urine.

By this time, we concluded that we were dealing with a case of insulin resistance of unknown cause. The patient continued to take large doses of insulin and continued to spill sugar and acetone. The acetone disappeared while the patient had six feedings with 50 units of regular insulin at each feeding; yet she continued to excrete large amounts of sugar in the urine. On May 21, she was discharged from the hospital with a diet of carbohydrate, 200 Gm.; of fat, 80 Gm.; of protein, 80 Gm.; with 60 units of insulin before each meal. She was closely watched at the clinic, and traces to 4 plus acetone began to appear in her urine. At this time a research bed was reserved at the New York Hospital.

Physical Examination.—On admission to the New York Hospital the patient was found to be moderately well developed, poorly nourished, showing obvious signs of great and recent weight loss. Intraocular tension was apparently normal, fundi were normal, and the tongue moist, showing no evidence of

Read at the Clinical and Pathological Conference at Gouverneur Hospital, New York City, November 19, 1942.

Chief of the Diabetic Clinic and assistant visiting physician, Gouverneur Hospital.

dehydration. Her skin was loose and dry. The lungs were normal; the blood pressure was 135/84; the liver was not palpated on admission but four days later it was definitely palpable 4 fingerbreadths below the costal margin.

Laboratory Data.—Urine on admission showed: *specific gravity of 1.027; acid; sugar, 4 plus;* acetone, 4 plus; no red blood cells; and no white blood cells. During the hospital stay, the urinary sugar remained 4 plus except for a few brief reductions to 1 plus or 2 plus. Urinary acetone disappeared after eighteen hours' treatment, reappeared on the fifth hospital day, and reappeared again on the seventh hospital day, reappearing finally on the tenth hospital day to remain at 4 plus until death.

Serology.—The Kline test was negative.

Blood Chemistry.—On admission examination showed a sugar content of 454 mg. On two occasions, the fasting blood sugar fell as low as 220 mg., although all other blood sugars taken during the hospital stay were over 500. Postmortem blood sugar was 937 mg. Blood carbon dioxide combining power, on admission, was 49 volumes per cent; twenty-four hours later it was 36 volumes per cent. A blood culture was negative. A flat plate of the abdomen was normal save for an enlarged liver. Skull plates showed a normal skull.

The patient was given 585 units of insulin on the day of admission, variable doses up to 900 units of insulin on the tenth day, and 1,310 units on the day on which dehydration, acidosis, and coma terminated the clinical course. She was given large amounts of fluids, from 1,900 cc. to 4,300 cc., and large amounts of carbohydrates—400 Gm., as an average. While insulin was given in large amounts on an hourly basis and the patient was comfortable and not spilling acetone, blood sugar levels showed a rising tendency instead of a declining one. On the thirteenth day of her stay at the New York Hospital, where she received individual care and study, the patient slipped deeper and deeper into acidotic coma. She expired with classical signs of diabetic acidosis and dehydration. Her breath smelled strongly of acetone, her skin was exceedingly dry, and her tongue was dry and coated. Her eyeballs were soft and sunken and her respiration deep and labored. She was in complete coma. Death was ascribed to diabetic acidosis.

Autopsy Findings.—The autopsy findings showed hyaline degeneration of the islands of Langerhans and fatty degeneration of the liver.

Experimental Work.—Experimental work done by Dr. E. Tolstoi is the most significant of all findings in this case. The following is the report of Dr. Tolstoi:

Problem: The patient entered the hospital requiring massive doses of insulin to keep her out of acidosis. Why? There was no fever, there were no stigmata of glandular dysfunction, and the possibility suggested itself that the patient had antibodies that destroyed insulin. To establish this point six experiments were performed. Since it is established that 0.02 unit of insulin produces convulsions in starved mice, experiments were planned to see whether the patient's serum would protect the mice against such convulsions.

Group A had nothing but 0.02 unit of insulin and 0.5 cc. of sodium chloride. The salt was used in order to have all volume uniform. All the injections were done intraperitoneally. The first injection was given at 2:55 P.M., the second at 2:56 P.M. At 3:20 P.M. the first mouse began to convulse, and, although alive, it could not walk but dragged its hind legs. At 3:55 P.M. the other one in this group revealed weakness of the hind legs. At 5:00 P.M. both of these animals were alive, having recovered.

In the experiment with Group B, 0.02 unit of insulin and 0.5 mg. of glucose were injected at 2:58 P.M. and 2:59 P.M. At 4:00 P.M. one animal developed convulsions and at 4:12 P.M., the other one began to drag the hind legs and to convulse. One of these animals died at 5:12 P.M.

Group C was given 0.02 unit of insulin and 0.5 cc. of normal serum at 3:04 P.M. and 3:05 P.M. At 3:30 P.M. the hind legs were unsteady in one, and at 4:00 P.M. paralysis and convulsions set in in the other. Both of these animals died.

In the Group D experiment 0.02 unit of insulin and 0.5 cc. of diabetic serum were injected at 3:07 P.M. and 3:09 P.M. At 4:45 P.M. one of these animals had a convulsion while the other was definitely slowed down and appeared ill.

Group E had 0.02 unit of insulin and 0.5 cc. of the patient's so-called resistant serum. The injections were given at 3:12 P.M. and 3:14 P.M., and at 5:12 P.M. both animals were extremely lively, neither showing any signs of illness. They were bouncing about the cage and were extremely active in searching for food.

One mouse was used for the Group F experiment, and only the patient's resistant serum was used. This was done to show that the serum itself was not toxic. The animal was perfectly well at 5:12 P.M.

Conclusions

1. The patient's serum had antibodies which protected the animal against insulin convulsions.
2. The serum of a diabetic patient, while not fully protective, nevertheless delays the onset.
3. Glucose solutions comparable to concentrations of 500 mg. per 100 cc. did not protect the animals against convulsions.

Discussion

The variability of response to insulin has been observed in nondiabetics by neuropsychiatrists in the treatment of schizophrenia. Similar variations are also known to occur in diabetics. It needs only to be pointed out here that the classification of diabetics into insulin-sensitive and insulin-resistant cases is well substantiated. The insulin-sensitive are young diabetics with acute onset; the insulin-insensitive or -resistant are the older diabetics, usually obese and arteriosclerotic, with insidious onset and a milder form of diabetes. This classification has been amply discussed by Falta, Himsworth, and De Wesselow. There are naturally exceptions to this classification, for even in the older group we may find thin and insulin-sensitive diabetics.

There are often variations in the response to insulin in the same diabetic, notably in cases of infections and diabetic acidosis, where large doses are required.

Normal physiologic insulin antagonists exist to maintain a dynamic equilibrium. Houssay, Long, and Young have contributed a great deal to a better understanding of the part that glands of internal secretion play in carbohydrate metabolism. Very large doses of insulin have been given in cases of hyperthyroidism, acromegaly, and Cushing's syndrome. Cases of hemachromatosis in terminal stages have required heroic doses of insulin.

Therapeutic approaches in t

doses of insulin are effective in infections. Similarly, large doses of insulin are lifesaving in the usual diabetic acidosis. The insulin refractory cases of diabetic acidosis reported by Marcel Labbe are questioned by Thannhauser[2] because he feels that a good many cases of diabetic acidosis in coma and in circulatory collapse would similarly prove to be insulin-resistant or -refractory. (Dr. Fabrykant, a former assistant of Dr. Labbe, informed me, however, that the cases reported by Labbe recovered from the diabetic acidosis through large doses of insulin but subsequently died of circulatory collapse.)

In the field of hyperactivity of known insular antagonists, thyroidectomies have served to overcome resistance to large doses of insulin in some diabetics. Celiac ganglionectomy has also been attempted. X-ray irradiation of the pituitary has been tried with variable results, and on a similar basis large doses of estrogenic hormone have been given in the attempt to suppress pituitary overactivity.

Lawrence refers to cases of known cause as "false insulin resistance."

In the *Klinische Wochenschrift* of February, 1933, Thannhauser differentiated two types of diabetic coma: *Insulinmangelkoma und Insulinrefraktäres Koma. Insulinmangelkoma* is diabetic coma due to insulin deficiency. *Insulinrefraktäres Koma* is insulin-refractory coma, a malignant type, which must be present for a longer period of time to be refractory, and which, without apparent cause, shows absolute resistance with positively no response to heroic doses of insulin.

Insulin resistance in insulin-deficiency coma is comparatively common in varying degrees, with varying complications, and the resistance disappears after the cause had been removed. In this group, we may include the case of Wiener[3], which required over 3,000 units of insulin during diabetic ketosis. The patient is now easily controlled with from 30 to 40 units of insulin daily and enjoys comparatively good health. A similar case presented by Glass, Spingarn, and Pollack,[4] required 2,360 units of insulin a day in diabetic coma and is now easily controlled with 5 units of protamine zinc insulin daily. The point made by Glass, Spingarn, and Pollack that very large doses should be resorted to in diabetic ketosis with insulin resistance is well taken and should be followed as a lifesaving procedure, as proved in their case and that of Wiener. One would naturally have to avoid a transition from diabetic coma to insulin shock and coma.

While resistance in insulin-deficiency coma is comparatively common, the insulin-refractory coma is fortunately very rare. The case we are reporting was an insulin-refractory type of diabetes.

An afebrile course, absence of endocrine stigmata (confirmed by autopsy), persistent high glycosuria, occasional ketonuria (difficult to deal with), higher blood sugars despite higher doses of insulin, the presence of insulin-neutralizing substances in the serum—are sufficient to classify this patient as an insulin-refractory case, although the mechanism is not fully understood.

Summary

An insulin-refractory case of diabetes mellitus was closely observed and studied for five months.

Death resulted from diabetic acidosis despite very high doses of insulin.

The clinical course was afebrile.

Allergic manifestations were present when the patient was first put on insulin.

Insulin-neutralizing substances were found in the serum of the patient.

Autopsy findings showed hyaline degeneration of the islands of Langerhans and fatty degeneration of the liver.

LEST WE FORGET

The Hippocratic Oath, still taken at some universities by graduates in medicine, is a code of ethics for physicians. It ends thus: "Whatsoever house I enter, there will I go for the benefit of the sick, refraining from all wrongdoing or corruption. . . . . Whatsoever things I see or hear concerning the life of men, in my attendance on the sick, or even apart therefrom, which ought not to be voiced abroad, I will keep silence thereon, counting such things to be as sacred secrets."—*Kentucky M. J.*

Case Report

PERSISTENT TYPHOID CARRIER FOLLOWING CHOLECYSTECTOMY CURED BY MEDICAL TREATMENT

ALEXANDER S. HONIG, M.D., New York City

THE following report concerns a typhoid carrier whose condition did not improve for a rather considerable period of time following surgical removal of the gallbladder, but who showed excellent response to proper medical therapy. This case emphasizes the necessity of specific medical management of this group of patients.

There is a certain hopeless attitude toward these typhoid carriers, who, after cholecystectomy, are not freed from the carrier state, but this paper illustrates a rather brighter aspect of the problem.

Case Report

A woman, 29 years old, was admitted to another hospital, complaining of acute pain of short duration in the midepigastrium. The past history of this woman revealed that five years prior to hospital admission she had had, on and off, pain in the epigastrium, distress, and some belching, for which she had been treated medically without relief. Examination revealed a temperature of 100 F., tenderness in the midepigastrium and right upper quadrant, with some upper abdominal boardlike rigidity.

The laboratory findings were: white blood cells, 11,600, with 81 per cent polymorphonuclear leukocytes; icterus index, 11.5. A week later the white blood cells were 6,400, with polymorphonuclears, 69 per cent. The clinical diagnosis was acute cholecystitis, with possible perforation. Ten days after admission, a culture of the feces showed the presence of typhoid bacilli, and a diagnosis of typhoid fever was made. Three weeks after admission the blood became positive for Bacillus typhosus. During her illness, the patient had several attacks of epigastric pain radiating to the back.

When the typhoid fever had subsided, cholecystectomy was performed. At operation, the gallbladder was found to be densely adherent to the omentum and was packed full of stones. The histologic examination showed chronic diffuse inflammation of the gallbladder with rupture of the wall. Culture of the gallbladder wall was positive for B. typhosus.

After removal of the gallbladder, the symptom of epigastric pain did not disappear, but instead it became worse. The patient had weekly attacks of epigastric pain, lasting from one-half hour to four hours, which were relieved by hot water or induced vomiting. The pain was sharp and colicky and was associated with belching, nausea, and vomiting. The symptoms were greatly aggravated by fried foods. Cultures of the feces continued to show B. typhosus. Examination and x-ray of the gastrointestinal tract disclosed no organic disease.

The patient was admitted to our special gallbladder clinic on November 1, 1939, over fourteen months after cholecystectomy. She complained of the above-mentioned symptoms and of her typhoid carrier status. The first duodenal biliary drainage, performed on the day of admission, showed a low concentration of bile salts, lack of free hydrochloric acid, and B. typhosus in the bile. The first bile specimen was obtained by means of the Twiss tube without stimulation. Two other specimens were collected after stimulation with 25 per cent magnesium sulfate (M specimen) and olive oil (O specimen), respectively. The bile sediment showed the presence of crystals of cholesterol.

These findings suggested a diagnosis of typhoid carrier status, common duct dyskinesia, and bile stasis. The patient received dilute hydrochloric acid (1 teaspoonful in 1/2 glass of orange juice) during meals. In addition, she took tincture of belladonna, 10 drops, and 1/2 grain of phenobarbital, three times a day after food. The next duodenal biliary drainage, three weeks later, did not show any substantial change, either in the clinical findings or in the laboratory data. The dose of tincture of belladonna was increased to 15 drops, and a low cholesterol, low fat diet was prescribed.

After three months on this regimen, all symptoms except belching disappeared. Duodenal biliary drainage was repeated. Cultures of bile specimens were reported negative for B. typhosus for the first time since the operation; however, some crystals were present, and the bile concentration was still poor. The next drainage, performed on March 1, 1940, showed a very good response to stimulation, a good concentration of the bile salts, a negative culture, and the disappearance of crystals from the bile. Clinically, the patient was completely free from symptoms. Repeated drainage and cultures (on March 13, March 18, and April 1, 1940) confirmed her complete clinical recovery and the disappearance of typhoid bacilli.

Discussion

On the grounds of history, operative findings, and postoperative course, we can assume that this patient suffered from disturbed function of the emptying mechanism of the gallbladder, caused by a spasm of the sphincter of Oddi, resulting in stasis of bile and formation of stones in the gallbladder. This condition was aggravated by a B. typhosus blood stream infection and acute typhoid cholecystitis years later. Removal of the gallbladder did not eliminate the underlying cause of the disturbance of the emptying function of the gall bladder. As a matter of fact, only a sequel of the dyskinesia (stone-packed gallbladder) was removed when cholecystectomy was performed, and the effect of the dyskinesia was just passed on to the common duct. The persisting spasm of the sphincter of Oddi and the associated periodic sudden distentions of the common duct only aggravated the biliary symptoms. It is ev

From the Clinic for the Study of Diseases of the Liver and Biliary Tract of the Department of Medicine and Surgery, New York Post-Graduate Hospital and Medical School, Columbia University.

*Follow-up visits.

there was such a stasis of the bile in the common duct as that indicated by a crystalline sediment, no infection would clear up. Our basic interest was focused on the dyskinesia. The treatment prescribed was for relief of the spasm of the sphincter of Oddi. This consisted of antispasmodics, sedatives, hydrochloric acid, and frequent feedings, resulting in a flushing out of the biliary tree. The repeated biliary drainages also helped to counteract biliary stasis. Since the typhoid cholecystitis and cholangitis were not of very long duration, the typhoid infection did not cause enough damage to the liver and to the inner lining of the biliary tree to destroy it and establish foci which could never be eradicated.

In this case the treatment could be successful only if a specific therapy was used to overcome the common duct dyskinesia. In uncomplicated typhoid carrier cases it is customary for the carrier state to clear up within three to four months after cholecystectomy. There are cases reported, however, which did not clear up until eight months after cholecystectomy. To our knowledge, the case here reported is one of the very few cases which cleared up eighteen months after the operation. We believe the success in this case was due to specific medical therapy. The hopeless attitude which condemns a persistent typhoid carrier following cholecystectomy as an eternal carrier should be revised. One should not spare patience and time in an effort to save these cases from a lifelong stigma.

Summary

1. A case is presented of a typhoid carrier whose carrier state cleared up eighteen months after cholecystectomy.
2. This, we believe, was due to specific medical therapy.
3. Attempts should be made with specific medical treatment to clear up the carrier state in patients who fail to become bacteria-free following cholecystectomy.

DETECTION OF MALINGERING

In a recent tissue of *War Medicine*, Dr. J. L. Fetterman, of Cleveland, describes two simple means of detecting malingering in patients.

The sincerity of a patient who complains of muscular weakness can be tested with a dynamometer, according to Dr. Fetterman, for the instrument measures accurately the muscular strength of the hand and arm. The patient is instructed to compress the instrument as firmly as possible. If, in an instrument that registers 100 or 150 kilograms for the average person, the reading is only 20 kilograms, the physician recognizes a case of hysterical paralysis or of deceit. He may further test the patient by asking him to grasp the dynamometer quickly but not forcibly. If the reading is then 150 kilograms or more, the exaggeration of weakness is revealed at once.

Dr. Fetterman's other test is used in detecting pain, a test involving the use of a tuning fork. The tuning fork is made to vibrate and is then placed over various regions of the body. The patient answers by stating whether or not the fork is vibrating. When he is cooperating fully, the examiner casually applies the tuning fork to the region of pain. Whether or not the fork is vibrating, the patient will mention the pain if he is sincere in his complaint. If not, he will merely observe the vibration or nonvibration of the fork.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. *The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.*

Plasma Therapy and Whole Blood Transfusion

AT A joint meeting of the Tioga County Medical Society and the staff of the Tioga County General Hospital, a single lecture on "Plasma Therapy and Whole Blood Transfusion" was given. The speaker was Ralph G. Stillman, M.D., assistant professor of medicine (clinical pathology) at Cornell University Medical College. The meeting was held at 6:30 P.M. on June 22 at the Wagner Hotel in Waverly, New York.

The same subject was discussed for the Warren County Medical Society by Frederick N. Marty, M.D., instructor in clinical medicine at Syracuse University College of Medicine, at a meeting held on May 20 at the Glens Falls Hospital in Glens Falls.

Arrangements for the lectures were made by the Council Committee on Public Health and Education of the State Medical Society and the State Department of Health in cooperation with the Medical Division of the Office of Civilian Defense and the Health Preparedness Commission of the State War Council.

General Medicine

AT A JOINT meeting of the Medical Society of Greene County and the staff of Memorial Hospital of Greene County, held on Thursday, June 24, Russell L. Cecil, M.D., professor of clinical medicine, Cornell University Medical College, spoke on "Arthritis—Acute and Chronic." The meeting took place at 9:00 P.M. at the Memorial Hospital of Greene County in Catskill, New York.

EDUCATIONAL TREATMENT FOR COLOR BLINDNESS

Discussing a technic which is claimed will educate men who are color blind so that they can pass the armed forces' tests for color blindness, the *Journal of the American Medical Association* for June 5 says that "Obviously, it is for the services themselves to determine whether or not the tests for color blindness now used are sufficient, in view of the possibilities of learning to screen out enough persons who are color deficient, or whether or not the young man who is willing to put in the necessary time in an educational process to learn enough about the tests to enable him to pass them would not qualify because of superior learning ability or intelligence to meet the needs of the armed forces. . . . .

"In the *Journal* for March 20 reference was made to an alleged cure for color blindness said to have been devised by one J. H. Lepper, optometrist, of Mason City, Iowa. Subsequent to the publication of that statement, Lepper sent to the *Journal* a communication in which he insisted that he does control color blindness in from fifteen to twenty days so that boys who followed his methods passed government tests. He submitted complete instructions as to the technic that he uses, some special lenses which are used as a part of the procedure, and a list of men now in the Navy and in the Air Force who had previously been rejected but were accepted after having followed his technic.

"The material concerned was referred to appropriate agencies in Washington, which verified the information supplied by Lepper as to the men who had been rejected and later accepted following his attention. Investigators then visited certain optometrists in the eastern part of the United States who follow the Lepper technic and studied their results.

"These investigators believe that Lepper is conducting an educational rather than a therapeutic process. In his technic the subjects are instructed to get some one with normal color vision to assist them and to trace the shapes of the figures carefully even in those charts in which they can see the figures fairly well. They are instructed to continue working on harder and harder charts and to keep daily records of the charts which they can read and those which they cannot read. Thus the person concerned builds a learning curve and with sufficient time masters the color manual thoroughly.

"It seems quite likely that those with disturbances of color vision do fix in their minds appearances which are associated with certain colors when viewing objects that have for them some familiarity. No doubt re-examination of these individuals at a later date, using a different technic, would reveal that the persons concerned are still color deficient, although they did learn enough about the test ordinarily used to pass that test and thus enable them to enter military service. . . . .

"The optometrists who are now specializing in the Lepper technic might limit their promotion of the method to the statement that they teach men to pass the tests for color vision and avoid carefully the use of the word 'cure' in any relation to color blindness."—*A.M.A. News*

Medical News

State Medical Schools Will Train Army Doctors

ACCORDING to an announcement made recently by the War Department, the commanding officer of the Second Service Command has been authorized to negotiate training contracts immediately with several New York State medical schools for the Army's specialized training program. Colleges on the list include:

College of the City of New York, Syracuse University, St. Bonaventure College, Niagara University, New York University, Fordham University, and Clarkson School of Technology, Potsdam, basic phase; New York University, advanced engineering; Cornell University, advanced personnel psychology; Albany Medical College, Columbia University School of Medicine, Long Island College of Medicine, University of Rochester School of Medicine, Cornell University School of Medicine, New York University School of Medicine, University of Buffalo School of Medicine, and Syracuse University School of Medicine; Columbia University School of Dentistry, New York University School of Dentistry, and University of Buffalo School of Dentistry; New York State Veterinary College; and Cornell University, premedical training.

Medical Society Formed to Exchange Information With Soviet Union

THE American-Soviet Medical Society has been founded to meet an increasing demand for information about the results and achievements of Soviet medicine. Reports have reached this country of spectacular feats of surgery wrought by the Soviet medical corps all along the far-flung battle line, from Leningrad to the Caucasus.

These contributions to medicine are the result of twenty-five years of untiring effort, during which the Soviet Union has built up an impressive system of public health and medicine. In hundreds of scientific research institutions behind the battle line, thousands of physicians and scientists are engaged in investigations. Yet the results are little known in this country, primarily because until now there has been no organization prepared to exchange medical information, although the language in many cases has proved an almost insurmountable barrier. The American-Soviet Medical Society will fill this gap.

Through meetings, the publication of a journal, and the establishment of a library of information, the Society will tell physicians of America and members of the allied professions on what problems our Soviet colleagues are working and what steps they are taking to solve them. On the other hand, the Society will send American medical books and periodicals to the Soviet Union in order to keep the Russians informed of scientific developments in this country and to stimulate closer cooperation between the medical corps of the two countries. After the war, as soon as conditions permit, the Society hopes to promote the exchange of students and scientists and to sponsor study tours in the two countries.

The Society gave a dinner in honor of Professor Vladimir V. Lebedenko at the Hotel Pennsylvania on Friday, June 18. Dr. Lebedenko is at present in the United States as Soviet representative of the Russian Red Cross. He is professor of surgery at the First Moscow Medical Institute and executive secretary of the Soviet Association of Surgeons.

The dinner marked the official launching of the American-Soviet Medical Society.

Among the speakers were Dr. Walter D. Cannon, professor emeritus of physiology at Harvard University and chairman of the Society; Dr. Henry E. Sigerist, director of the Institute of the History of Medicine at Johns Hopkins University and editor of the Society's forthcoming journal, the *American Review of Soviet Medicine;* as well as representatives of the United States Public Health Service and of the New York City Department of Health.

The president of the Society, Dr. Walter D. Cannon, is a member of the National Academy of Sciences of the United States and of the Academy of Sciences of the U.S.S.R.

The temporary offices of the Society are at 130 West 46 Street, New York City.

Maternity and Infant Care for Wives and Infants of Men in the Armed Forces

MATERNITY care for wives of men of certain grades in military service and medical and nursing care for their babies can now be provided without cost to the family through state health departments under plans approved by the Children's Bureau. Funds for the next few months have already been voted by Congress in a bill signed by the President on March 18, 1943.

Under this plan a pregnant woman may receive prenatal care from a qualified doctor of medicine in a clinic or at his office. At childbirth, whether she stays at home or goes to a hospital, she and her baby may receive medical and nursing care. Complete maternity care may be provided, including a final physical examination six weeks after the baby is born, and the baby may receive medical care during the first year of life.

In states providing these services, the wife and infant of any man serving in the fourth, fifth, sixth, or seventh grade of the Army, Navy, Marine Corps, or Coast Guard are eligible for care as long as similar services are not available through medical or hospital facilities of the Army or Navy or by or through official state or local health agencies.

How long the wife has lived in the state does not matter. How much money the family has does not matter. Race or color does not matter.

County News

Albany County

Dr. Leonard G. Stanley, of Albany, is celebrating his fortieth year as a doctor-orchestra conductor. Instead of giving up his musical interests after he had worked his way through medical school by playing the violin, Dr. Stanley organized a community orchestra and became its conductor. Since the group was founded, the orchestra members have met once a week during the winter seasons to rehearse. Their anniversary was observed with a regular weekly concert, followed by a banquet at the DeWitt Clinton Hotel in Albany.

Broome County

Approximately 175 persons who require additional or special foods to meet medical and dietary requirements are now receiving supplemental food rations under a plan inaugurated by the Eastern Broome County War Price and Rationing Board.

The plan was developed by the board's food panel, representatives of the Broome County Medical Society, and dieticians, and is aimed at providing foods for ailing persons who would be unable to maintain proper diets without supplemental allowances.

The program is one of the major projects of the food panel and has been instituted with the assistance of a medical society committee consisting of Drs. Howard W. Davis, and M. S. Bloom, working with Morris Gitlitz, panel chairman.*

• • •

Led by William H. Mellor and Dr. Ralph M. Vincent, members of the executive committee of the Broome County Tuberculosis and Public Health Association and the public health committee of the Broome County Medical Society recently inspected the mobile x-ray unit which was in operation for employees at Ozalid.

After looking over the state-owned equipment, members of the two committees were guests at luncheon in the Ozalid cafeteria.

Dr. Vincent's committee consisted of Dr. Vesta Rogers, Dr. C. J. Longstreet, Dr. Irving Werner, Dr. Walter J. Farrell, Dr. A. J. Stillson, and Dr. S. E. McManis.*

Cayuga County

The county society has started a project to secure the complete records of members of the society who are in the military service of their country, for preservation in the archives of the society.

The work has been started by a special committee composed of Dr. C. F. McCarthy, chairman and historian of the society, Dr. Bernard L. Cullen, Dr. Leonard H. Rothschild, and Dr. Frank L. DeFurio.

The society has had members in the War of the Revolution, the War of 1812, the Mexican War, the Civil War, World War I, and now there are nearly 30 members serving in World War II.

Dr. McCarthy has mailed to all physicians now serving a comprehensive questionnaire, covering education, private practice, hospital affiliations, membership in professional associations, and military service.*

Chemung County

The Prepayment Medical Service Plan of the Blue Cross Group Hospital Insurance Inc. was explained to the Chemung County Medical Society by a Blue Cross representative at a meeting held on June 2 at the Arnot-Ogden Hospital.

The society has been studying medical service plans for several months.*

Dutchess County

The final meeting of the season of the county society was omitted. The meeting, which would have included the annual outing, was called off on account of gasoline rationing restrictions, Dr. Emil A. Stoller, society president, said.

In the place of the annual outing and scientific program, a business meeting was held on June 9.

In connection with the war effort, Dr. Stoller said the society has purchased $2,000 worth of war bonds from accumulated funds of the organization.*

Erie County

In cooperation with the movement begun by the National Noise Abatement Council, Buffalo has set up a local committee to organize a drive against unnecessary noise in war industrial plants, offices, and homes. The program was opened with a concentrated campaign during National Noise Abatement Week, from May 30 to June 5.

Members of the committee are W. L. Fetch, chairman; Dr. Herbert H. Bauckus, president-elect of the New York State Medical Society; Dr. Francis E. Fronczak, health commissioner; Police Commissioner Charles E. Cannon; Harry I. Good, associate superintendent of schools; Councilman Russell J. Leech; and C. G. Travers, Claude J. Brumbaugh, Joseph N. Lopes, Ray Pendleton, Fred W. Fogg, and George Prong, of the Buffalo Chamber of Commerce.

• • •

Dr. Albert H. Garvin was re-elected president of the Buffalo and Erie County Tuberculosis Association at the annual meeting in May. Dr. Horace LoGrasso was re-elected a vice-president.

Officers of the association reported that because of crowded housing accommodations and other results of the war, the death rate from tuberculosis increased from 47 deaths per 100,000 population in Buffalo in 1940 to 54 per 100,000 in 1942.*

• • •

Dr. Harold J. Welsh, of Buffalo, has been appointed deputy county physician (medical examiner) by Commissioner of Charities and Correction Fred L. Heitzmann, to succeed Dr. Wallace R. Stewart, who has resigned.

Dr. Welsh has served on the pathology staffs of New York, Memorial, and Bellevue hospitals and the Cayuga County Laboratory in Auburn City Hospital.*

• • •

Dr. Harold F. R. Brown, president, reports that the county society's comitia minora has accepted with regret the resignation as first vice-president of Dr. John D. Naples, now in the Army Medical Corps in California, and has elevated Dr. P. H. J. Buckley from the second vice-presidency to that post. A second vice-president is to be named.*

• • •

* Asterisk indicates that item is from local newspaper.

At the age of 81, Dr. Lawrence G. Hanley, who has practiced medicine in Buffalo for fifty-six years, has no thought of retirement and keeps up with a full load of work. A graduate of Niagara University, from which he holds five degrees, Dr. Hanley has also studied in Europe. He is a member of the American Medical Association, the Erie County Medical Society, and the Buffalo Academy of Medicine.

Kings County

Some 100 Brooklyn and Long Island surgeons, members of the Brooklyn and Long Island Chapter of the American College of Surgeons, watched a series of operations in the New York Post-Graduate Medical School and Hospital on May 22.

The surgeons made their observations in the amphitheater of the Medical School during several of the operations and others were performed in the large operating rooms of the hospital. In the amphitheater Drs. J. William Hilton and Thomas H. Russell, the latter chief surgeon of New York Post-Graduate, performed operations regarded as rare feats of surgery.

In the evening the Brooklyn and Long Island surgeons entertained those of the New York Post-Graduate Medical School and College who had participated in the actual demonstrations and scientific discussions at dinner at the Waldorf-Astoria.

Dr. Charles A. Gordon, president of the Brooklyn and Long Island Chapter, and Dr. John F. Raycroft, chairman of the scientific committee, arranged the program, assisted by Dr. Robert F. Barber, the vice-president, and Dr. Merrill N. Foote, secretary-treasurer.

In the gathering were the following Brooklyn surgeons: Drs. Thomas Brennan, Walter A. Coakley, head of the medical board of the Kings County Hospital; Ralph Lloyd, Charles Mueller, Louis Berger, Milton Bergmann, Laurence Bodkin, Benjamin Cissel, Julius M. Dan, George H. Davis, S. Lloyd Fisher, John J. Gainey, Edwin J. Grace, Harry Greene, Augustus Harris, William Linder, Joseph M. Linett, Frank E. Mallon, A. W. Martin Marino, George Marsh, Robert Moorhead, Joseph Nevins, Samuel Parnass, Anthony Pirundini, Nunzio Rini, Joseph Tenopyr, and Ottokar Tenopyr.

Among the Long Island men were Drs. William Bartels, Hempstead; Lawrence Breitbart, Flushing; Charles Murphy, Amityville; Joseph Connolly, Glen Cove; John M. Scannell, Jamaica; J. H. Hulka, Long Island City; and Frank S. Child, Port Jefferson.*

• • •

Dr. Thomas A. McGoldrick, president of the Medical Society of the State of New York, was one of the recipients of the Brother Thomas Memorial Medal at the commencement exercises of Manhattan College.*

• • •

Dr. John J. Gainey, president of the Kings County Medical Society, has become a member of the City Committee to Study a Plan to Provide Medical Service for People in Moderate Circumstances.

Dr. Gainey was invited by Mayor F. H. LaGuardia to serve as the Brooklyn representative. The committee is made up of medical society representatives and employer groups and was formed to work out a cooperative medical group insurance plan. *

Monroe County

Dr. William A. Sawyer, medical director of Eastman Kodak Company, was named 1943 recipient of the Knudsen Medal for "the most outstanding contribution of the year to industrial medicine."

The award, established in 1939 by Lieutenant General William S. Knudsen, then president of General Motors Corporation, was presented at a dinner of the American Association of Industrial Physicians and Surgeons. Selection of Dr. Sawyer was made by a committee of past medal winners.

The physician was cited for his "outstanding work in control of tuberculosis, constructive contributions to a practical program of nutrition in industry, and setting up a program of rehabilitation for handicapped workers in industry."

Dr. Sawyer, a native of Iowa and a graduate of the University of Pennsylvania Medical School, has devoted his entire career to industrial medicine. After two years with Philadelphia firms, he joined Eastman in 1919.*

• • •

Notwithstanding rationing, Americans are sure to have well-balanced amounts of food in 1943, and "the slight reduction in calories will do us more good than harm," Dr. John R. Murlin, head of the department of vital economics of the University of Rochester, told the county society at a meeting held on May 18 at the Rochester Academy of Medicine.*

• • •

According to Dr. J. F. McCahan, chairman of the Rochester committee on Noise Abatement, noise is responsible for errors, a statement that Dr McCahan substantiated with figures on the improvement shown in offices in which noise has been reduced.

Dr. G. Kirby Collier, neurologist and president of the Medical Society of Monroe County, also pointed out that noise produces physical harm that is more serious than we generally suspect.

Dr. McCahan was the speaker at a meeting of the Rochester Chamber of Commerce Health Conservation Committee during the recent Noise Abatement drive in Rochester.

• • •

Dr. Achsa Bean, a physician who served for a year as a major in the Royal Army Medical Corps in London and York, England, has received a commission as a lieutenant (j.g.) in the Waves.

Dr. Bean, now stationed at the Naval Training School (Women's Reserve), the Bronx, is one of the first physicians to join the Waves. She was in England from August, 1941, until August, 1942, and was in charge of men's wards in Army hospitals.

Dr. Bean was graduated from the University of Maine and received her M.D. degree from the University of Rochester School of Medicine in 1936. After serving as an instructor in medicine at the University of Rochester, she went to Vassar College as assistant chairman of the department of health and hygiene.*

Nassau County

Dr. Nathaniel H. Robin, of Hempstead, will take over the presidency of the Nassau County Medical Society July 1. He was installed at the organization's annual meeting in the Nassau Hospital auditorium, Mineola, on May 25.

Other officers elected at the annual session are the following doctors: Austin B. Johnson, of Cedarhurst, president-elect, to take office in 1944; William C. Atwell, Great Neck, vice-president; E. Kenneth Horton, Rockville Centre, secretary-treasurer; delegate to the state medical society for two years, Louis A. Van Kleeck, Manhasset.

On the board of censors are Drs. John M. Galbraith, of Glen Cove; Stephen F. Gerde, of Freeport; A. Milton Goldman, of Rockville Centre; James L. Winemiller, of Great Neck; and Charles Edwin Woods, of Westbury.

Elected to the workmen's compensation board for two-year terms are Drs. B. L. Burdick, of Rockville Centre; Harold A. Butman, of Manhasset, and Otho C. Hudson, of Hempstead.*

• • •

The Nassau County Health Department held an anniversary dinner at the Garden City Hotel on May 18. More than 100 were present. Speakers included Dr. Benjamin R. Allison, chairman of the County Health Board; Dr. Earle G. Brown, Nassau County Health Commissioner; County Executive J. Russel Sprague; Dr. Edward S. Godfrey, Jr., New York State Health Commissioner; Dr. Ernest L. Stebbins, New York City Health Commissioner.

Dr. R. C. Williams, of the U.S. Public Health Service; Dr. E. N. Whitcomb, president of the Nassau Medical Society; and Dr. H. E. Meleney, professor of preventative medicine at New York University, were also speakers.

New York County

The Welfare Council, 44 East 23 Street, Manhattan, has on hand a limited number of copies of *Chronic Illness in New York City* by Mary C. Jarrett, a study in two volumes made by the Council's Research Bureau. These books are available to physicians and agencies to whom they may be useful. The only charge made will be for wrapping and mailing, amounting to about twenty cents.

• • •

The Department of Ophthalmology of the College of Medicine of New York University announces that because of its educational program associated with the war effort the nine months' Graduate Course in Ophthalmology will be discontinued for the duration of the war.

• • •

The Phi Delta Epsilon Medical Fraternity sold $600,000 in war bonds during the last drive. A luncheon celebration was held at the Waldorf-Astoria Hotel, Saturday, June 5, when Treasury Department officials named two heavy bomber planes in honor of the Fraternity.

• • •

The Eighth Annual Convention of the National Gastroenterological Association was held on June 2 at the Hotel Astor in New York City.

Dr. Anthony Bassler, president, of New York, presided at the scientific sessions. Included in the day's program was a military luncheon at which Lt. Comdr. Michael Lake, M.C., USNR, discussed "Peptic Ulcer in the Navy."

• • •

Dr. Axel Leonard Melander, chairman of the department of biology at the College of the City of New York and owner of one of the country's largest private collections of diptera, or winged flies, will retire at the end of the present semester. Dr. Melander, who will be 65 years old in June, came to City College from Washington State College in 1926. He was made chairman of the biology department in 1928.

A graduate of the University of Texas, he obtained the degree of Doctor of Science from Harvard University in 1914. Afterward, he taught biology for twelve years at Washington State College.*

• • •

One hundred underprivileged diabetic children of this city and adjacent communities left New York on July 1, the opening day of Camp Nyda at Wallkill, New York, where they have spent a two-week vacation. The New York Diabetes Association, a group of leading specialists on diabetes, is sponsor of the camp.

The Association announced that the number of youngsters to be accommodated depended upon the response to the appeal for funds that the association was making. To care for the children this year it was estimated that $7,000 would be needed.*

• • •

A plan whereby indigent persons would be cleared through a central municipal registration bureau and physicians would be paid by the city for their treatment has been adopted by the executive heads of the Medical Society of the County of New York.

At present, the city's medically indigent are treated at public and private hospitals, at home, and in the offices of physicians, but there is no systematic clearing of the patients to prevent duplication of service, and physicians are not remunerated for their services, it was stated by Dr. Charles Perera, chairman of the society's Special Committee on Education and Publicity.

Under the plan, a central municipal registration bureau would be established, with a paid physician as chief executive.

This bureau would come under a nongovernmental, nonprofit agency or corporation, to be set up with the cooperation of the city government. The board of directors would consist of one-third city officials, one-third physicians selected or appointed by the five county medical societies of Greater New York, and one-third prominent laymen acceptable both to physicians and government representatives. The medical members would constitute the medical policy committee. There would be no change in the medical policy without the consent of the medical policy committee.

In order to qualify for treatment as an indigent, a single person would have to have an annual income of $1,000 or less, the committee decided.

The income of a man and wife would have to be $1,450 or less and the allowance for each dependent would be $250, not to exceed $1,950 for a family. These rates would be adjusted at the discretion of the policy committee. The bureau would require an annual certificate of registration.*

Oneida County

At the Utica Academy of Medicine's May meeting, Dr. Maurice J. Costello, assistant dermatologist and syphilologist, Bellevue Hospital, New York City, spoke on "Sulfonamide Therapy in Dermatology." Discussion was opened by Dr.

H. D. Parkhurst. Dr. O. J. McKendree, of Utica State Hospital, had as his subject "Wartime and Psychiatry." Discussion of his address was opened by Dr. L. L. Bryan, of Marcy State Hospital. A tribute was paid the late Dr. Andrew Sloan, who was the first president of the Academy of Medicine. Dr. Ross Helmer, Utica State Hospital, presided.

The town of Rome recently conducted a campaign for the prevention of diphtheria, the goal of which was to immunize all Rome children between the ages of 6 months and 12 years.

• • •

Dr. Karl W. Gruppe, major in the Army Medical Corps, has been honorably discharged and has resumed his practice in Utica.*

• • •

Dr. Max Gara, a graduate of the University of Vienna, has been appointed village physician for New York Mills.

Dr. Gara was head surgeon of the Workmen's Compensation Hospital, Vienna, for twelve years. His American internship was served in Medical Center, Jersey City. He also served as resident physician at Memorial Hospital, Manchester, Connecticut.

He comes to New York Mills from New York City through the cooperation of Dr. H. D. MacFarland of the Oneida County Medical Society procurement and assignment committee, the Village of New York Mills having been without a resident physician for several months.*

Ontario County

Dr. Harry M. Smith entertained the Canandaigua Medical Society at dinner and provided the program for the May meetin[illegible] Hotel. He showed colored [illegible] talked on the seashells of Florida, and also showed scenic views.

Dr. E. C. Merrill, vice-president, presided in the absence of Dr. Margaret T. Ross. Guests were Dr. H. R. Hageman, Palmyra, and Drs. Ludwig Mayer, Hans Hansen, and Augustus W. Sainsbury, of Canandaigua.

Dr. Merrill was host to the June meeting of the society on June 8 at his home. Dr. W. C. Eikner, of the Clifton Springs Sanitarium staff, read a paper on "The Prostate," as speaker for Dr. John H. Pratt.*

Queens County

A joint meeting of the county society and the Queens County Bar Association was held on Tuesday, May 25, at 8:30 P.M. The program was opened with remarks by Mr. Bernard J. Ferguson, president of the County Bar Association. The scientific addresses included: "The Doctor in the Court Room," by Honorable Joseph M. Conroy, county judge in Queens County; "Some Psychiatric Problems Common to the Practice of Law and Medicine," by Carl Binger, M.D., assistant clinical professor of medicine, department of psychology at Cornell Medical College; and "Medicolegal Significance of Histologic Examinations," by Dr. B. M. Vance, deputy chief medical examiner of the city of New York.

Dinner at Forest Hills Inn at 7:00 P.M. preceded the program. The guest speakers were present at the dinner.

• • •

Expansion of tuberculosis education, including x-ray activities and six new control projects, to meet current and postwar needs, has been decided upon by the board of directors of the Queensboro Tuberculosis and Health Association for its 1943 program, Dr. James R. Reuling, of Bayside, president, has announced. The proposals were drawn up by the Plan and Scope Committee, headed by Dr. H. McLeod Riggins, medical director at Triboro Hospital for Tuberculosis.

The association's Industrial Chest Service, which heads the list of projects is designed to combat tuberculosis among war workers and their families.

A special survey of present and postwar hospital needs for the tuberculous in New York City will be undertaken this year in cooperation with the Greater New York Tuberculosis and Health Advisory Committee.

The association will begin a project of education among patients already in tuberculosis hospitals. Among other new projects is a demonstration of tuberculosis case-finding in general hospitals in Queens.

A system of postgraduate study in tuberculosis for Queens doctors, with scholarships to be awarded by the association, was recommended by the board.

Plans were adopted for expansion of the rehabilitation department and the addition of personnel to reach more patients recovering from tuberculosis.

Dollar x-rays for the general public, Negro health work, consultation chest clinics, and surgical research will be continued and extended.*

• • •

The charter members of the Rockaway Medical Society recently celebrated the twentieth anniversary of the founding of the organization with a dinner given to Dr. Martin L. Sowers, a former president and one of the organizers of the Society, at the Seawane Golf Club, Hewlett Harbor.

The dinner was given on the occasion of Dr. Sowers' fiftieth birthday. Those attending the celebration included members of the medical and surgical profession practicing in the Rockaways who were members of the Society when it was organized.

Dr. Joseph Baum, of Woodmere, formerly of Far Rockaway, acted as master of ceremonies, while Dr. Leonard S. Rau, formerly of Lawrence, Long Island, and now of Manhattan, was one of the speakers.*

• • •

A series of articles prepared by the Child Welfare Committee of the county society, "designed to provide timely advice to parents," has been published in the Long Island press. Among the topics covered in the series are skin rashes, smallpox, diphtheria, whooping cough, tetanus, typhoid fever, scarlet fever, measles, the common cold, and infantile paralysis.

• • •

Dr. Frank L. Babbott, former president of the Long Island College of Medicine, has been elected chairman of the college board of trustees, to succeed Henry A. Ingraham.*

Rensselaer County

Dr. Harriet E. Kenney, school physician at Cohoes, has officially retired on pension, at the age of 70.

Dr. Kenney has been medical supervisor in the public schools of the city for more than a quarter of a century.

A gift of a purse was presented to Dr. Kenney on behalf of the principals, teachers, and administrative staff members of the Education Department.

Dr. M. J. Keough, who has served as health commissioner of the city for a number of years, will assume the post.

• • •

Schenectady County

The semiannual meeting of the county society was held at the Mohawk Golf Club on Thursday, June 3. Dinner, which was served at 7:00 P.M., was preceded by a business meeting. Speaker of the evening was Dr. N. A. Pashayan, who gave an illustrated talk on "Egypt and the Holy Lands."

Seneca County

The regular semiannual meeting of the county society was held at the Armitage Tea Rooms in Seneca Falls on May 13. At the scientific sessions, which took place in the afternoon, Dr. J. G. Fred Hiss, of Syracuse, spoke on "Rheumatic Fever and Its Complications," and a demonstration blood transfusion was given by representatives of the Upjohn Company.—*F. W. Lester, M.D., Secretary*

Steuben County

Dr. Carl G. Schwan was elected president of the Hornell Medical and Surgical Society at the annual banquet and meeting on May 12 at the Hornell Country Club. Dr. D. Roger Haggerty, of Arkport, was elected vice-president and Dr. James I. Yanick, secretary-treasurer. There were 26 members present.

Dr. C. E. Patti, the retiring president, who served for two consecutive years in office, presided and offered a toast of tribute to members now serving in the armed forces. They are: Maj. Arthur Karl, Maj. Thomas Cotton, Capt. James MacFarland, Capt. Charles Rose, Lt. Richard Travis, Lt. Alphonse Lucas, and Lt. (j.g.) Leon Roe.

Lieutenant Roe, the only serviceman member able to be present, was home on leave from Fisher's Island and visiting at his home in Canisteo. He spoke of his experiences with medicine in the Navy and answered inquiries of guests concerning his training and work.*

• • •

The summer meeting of the county society was held Thursday, June 10, at the Hotel Wagner, Bath. Luncheon at 12:30 P.M. was followed by a business meeting at 1:30 P.M.

Dr. R. J. Shafer, of Corning, spoke on "Sesame and Peanut Oil Cysts." The new Farm Security Administration contract and the Medical Insurance Plan were also discussed.*

Suffolk County

Officers and directors of the Suffolk County Tuberculosis and Public Health Association were elected at meetings of that organization on Tuesday, May 25. The officers elected for the coming year are as follows: Dr. Frank S. Child, president; Frank B. Smith, first vice-president; John H. Aldrich, second vice-president; Mrs. Allan Heath, third vice-president; John S. Howe, treasurer; and Earl P. Rubini, secretary.

Directors elected to serve for a three-year period are as follows: Mrs. B. V. Burdge, Huntington; Dr. Frank S. Child, Port Jefferson; Mrs. J. Henry Daily, Babylon; Dr. David Edwards, East Hampton; Mrs. Joel S. Lawson, St. James; Mrs. Verne L. Rockwell, Smithtown Branch; Frank B. Smith, East Hampton; Earl P. Rubini, Southampton; and Capt. George H. Monsell, Cutchogue.*

• • •

Dr. William H. Ross, of Brentwood, observed his fifty-fifth year in the practice of medicine in June. He began his internship at Presbyterian Hospital, New York, in June, 1888, after graduating from Columbia University College of Physicians and Surgeons.

Dr. Ross was recently elected chairman of the Board of Trustees of the New York State Medical Society. He has already served two terms in this capacity, having been a trustee of the medical society continuously since 1928, except for the two years he retired to serve first as president-elect of the society and then as its president. The chairmanship of the Board of Trustees carried with it membership on the newly formed Planning Committee for Medical Policies but Dr. Ross declined this honor and designated another member of the Board of Trustees to serve in his place.

Dr. Ross, who has steadily advocated medical leadership for the important problems in medicine arising from the demands of a "rapidly changing world," foretold these changes in an article published in the *Long Island Medical Journal* twelve years ago, when the present trends were barely discernible. This prediction, now a reality, was recently quoted in the NEW YORK STATE JOURNAL OF MEDICINE.*

• • •

Dr. Joseph H. Werk formerly of Bohemia, New York, will move to Port Jefferson, about the first of next month, augmenting the medical staff of the village, which has been decimated by several members of the profession entering the armed services of the country.

Dr. Werk has been a practicing physician in Bohemia since 1939. He was born in New York City in 1909 and graduated from the De Witt Clinton High School. He took his degree of B.S. at the City College of New York in 1930, and his medical degree at the University of Glasgow, Scotland, in 1935. His internship and residencies were at the Bronx Hospital and Physicians' Hospital in New York City.

The doctor is a member of the Suffolk County Medical Society and is on the staff of the Mather Memorial Hospital.*

Sullivan County

Dr. Nathan Nemerson, eye, ear, nose, and throat specialist, has opened an office in Monticello.

The doctor, who has practiced at South Fallsburg the past sixteen years, is a graduate of New York University, where he received his degree of Bachelor of Science, and of Cornell University, where he was awarded the degree of Doctor of Medicine in 1926.

He is vice-president of the Sullivan County Medical Society; a member of the New York Academy of Medicine; and a member of the New York Society for Clinical Ophthalmology. He has been certified as a specialist by the American Board of Ophthalmology.*

Warren County

The semiannual meeting of the Warren County Medical Society was held Thursday, May 20, in the auditorium of the Glens Falls Hospital at 8:30 P.M. Routine

mittee was appointed to study the matter of Medical Expense Insurance and to report at the next meeting.

The speaker of the evening was Dr. Frederick N. Marty, instructor in clinical medicine, Syracuse University, College of Medicine, who spoke on "Plasma Therapy and Whole Blood Transfusions." This program was part of the postgraduate instruction arranged by the Council Committee on Health and Education of the Medical Society of the State of New York and the New York State Department of Health in cooperation with the Medical Division of the Office of Civilian Defense and the Health Preparedness Commission of the State War Council.

Thirty-five members were present. The lecturer was well received, and a very interesting discussion followed his address.—*Morris Maslon, M.D., Secretary-Treasurer*

Westchester County

Dr. Lester Wartels, recently retired from active service as a captain in the Army Medical Corps following a surgical operation, has been appointed assistant city physician in New Rochelle, to succeed Dr. Raymond Shea, who has left for active duty in the Army. Dr. Clifford H. Fulton holds the position of city physician.*

• • •

The following resolution was passed recently by the Westchester County War Council:

"WHEREAS, since June, 1940, when he became chairman of the Medical Preparedness Committee of the Westchester County Medical Society, Dr. Erich H. Restin has devoted his attention to [illegible] Emergency Medical Service [illegible] County, and

WHEREAS, he has been unsparing of his time in this vital public service, and

WHEREAS, conditions beyond his control have necessitated his resignation as Director of Emergency Welfare Service for Westchester County; now, therefore be it

Resolved, by the Westchester War Council, that this expression of public appreciation of the devoted and able services of Dr. Erich H. Restin, as Director of Emergency Medical Service of Westchester County, be made a part of the official transactions of this Council and that a copy of this resolution be sent to the press and to Dr. Restin.*

• • •

Dr. Ralph T. B. Todd, of Tarrytown, is serving as chairman of the Westchester Medical Advisory Board for the local branch of Planned Parenthood Federation of America, which is now conducting a drive to raise $2,400. Other physicians serving on the Board include, Dr. William J. Vogeler, of Yonkers; Dr. Francis Giammatei, of Tarrytown; Dr. Wilbur W. Stearns, of Yonkers; Dr. Waring Willis, of Bronxville; and Dr. Edwina Kittredge, of Yonkers.

OCD Advises Gas Cleansing Stations at Hospitals

HOSPITALS should make complete plans for the immediate establishment, when needed, of "gas cleansing stations" for the care of injured persons who have been exposed to war gases, the Medical Division of the Office of Civilian Defense advises in Operations Letter No. 124 (Supplement No. 4 to Operations Letter No. 42). Large communities should establish at least one gas cleansing station without delay for training purposes.

The OCD recommends that the term "gas cleansing" be used to describe the procedure of removing vesicant liquids from persons and that the term "decontamination" be reserved for areas and objects.

The primary purpose of gas cleansing stations is the protection of hospitals and casualty stations and their staffs and patients from contamination by injured persons who have been exposed to vesicant agents, the Operations Letter points out. Contaminated persons who are not disabled are expected to cleanse themselves in the nearest private home or in other local facilities.

Existing facilities in casualty receiving hospitals must be converted into gas cleansing stations, it is pointed out, since under present conditions of scarcity of materials and manpower, construction of new facilities is generally not justified. Hospital facilities that should prove suitable are suggested as follows: hydrotherapy rooms, nurses' or interns' locker and shower rooms, part of the outpatient department, garages, or other separate structures. In the event that these are not available, facilities to care for persons who are both injured and contaminated must be arranged in schools, gymnasiums, swimming pools, shower rooms, club houses, and community centers.

Cleansing stations should be equipped to take care of one-third to one-half of the hourly casualty receiving capacity of the hospital to be served, the OCD recommends. The professional staff will consist of Mobile Medical Teams assigned when the station is activated, supplemented by additional attendants from the Emergency Medical Service. In addition to cleansing and emergency treatment, the staff of the gas cleansing station will assist in undressing the injured, moving stretchers, caring for clothing and valuables, maintaining supplies, and dressing wounds.

It is recommended that cleansing stations be established at or near hospitals and casualty stations which they are to serve. Every hospital that may be required to handle an appreciable number of casualties should have access to such cleansing station facilities.

The local Chief of Emergency Medical Service is responsible for the development of these stations, with the advice of the Senior Gas Officer of the community.

Improvements

An oxygen tent and two bedside tables have been donated to the Ossining Hospital by the Woman's Auxiliary.*

• • •

General Electric x-ray engineers have completed the installation of new x-ray equipment at St. Jerome Hospital in Batavia.*

• • •

Mount Vernon Hospital has installed ultraviolet germicidal lamps in two nurseries on its maternity floor. Funds for the installation were contributed by the woman's auxiliary of the hospital, which also recently contributed $450 for the purchase of another incubator for premature infants.

All parts of the nursery are now irradiated twenty-four hours a day. In 1942, 1,048 babies were born in the Mount Vernon Hospital and in the first three months of this year 280 babies have been born at the hospital, 30 more than during the same period in 1942.

• • •

Three rooms have been added to the x-ray department of St. Agnes Hospital in White Plains, and new equipment has been installed for diagnostic and therapeutic purposes.

The War Production Board granted a priority for two diagnostic machines, a superficial treatment machine, and deep therapy equipment for treating cancer and other diseases.

The shockproof therapy equipment has safety devices insuring safety and comfort for patient and operator. The main diagnostic room has a generator with a rotating x-ray tube. The auxiliary radiographic room has a generator with a tilting table and spot film device for radiographs of the gastrointestinal tract. The x-ray department is directed by Dr. Charles Wadsworth Schwartz.*

POTENT . . . UNDILUTED . . .

Natural B Complex

LIQUID

B COMPLEX SYRUP SQUIBB

An undiluted rice bran extract, with thiamine and riboflavin added. Extract of Rice Bran is official in U. S. P. XII. The Squibb product meets U. S. P. requirements in every respect except that its specific gravity is slightly higher.

One teaspoonful (5 cc.) supplies 1.5 mg. thiamine hydrochloride; 1 mg. riboflavin; 12.5 mg. of a naturally occurring mixture of niacin and niacin amide; 0.75 mg. pyridoxine hydrochloride and 1.4 mg. pantothenic acid. Calories 2.56 per gram.

POWDER

NATUPLEX-B . . . Squibb Extract of Natural Vitamin B Complex derived from high-potency brewers' yeast — unfortified, undiluted. Makes possible the administration of the "natural" vitamin B Complex in heavier dosage than hitherto *regarded as practicable.*

Average daily dose of one heaping teaspoonful (10 grams) supplies 5 mg. thiamine; 2 mg. riboflavin; 20 mg. niacin; 1.6 mg. pyridoxine; 5.3 mg. pantothenic acid; 32 calories.

TABLETS

B COMPLEX TABLETS SQUIBB

A product of choice for correction of milder forms of B Complex deficiency conditions, and for maintenance. Two tablets supply the full daily allowance of B_1, B_2 and niacin amide as recommended by the Food and Nutrition Board of the National Research Council.

Each tablet contains 5 grains Natuplex-B together with 1 mg. thiamine hydrochloride; 1.5 mg. riboflavin and 10 mg. niacin amide.

These and other individual and multivitamin products are available from the Squibb Laboratories. Write for the Squibb booklets, "Vitamin B Complex Therapy" and "Squibb Vitamin B Complex Products." Address the Professional Service Department, 745 Fifth Avenue, New York 22, N. Y.

staff of the Hospital for Joint Diseases. She is a graduate of the Lebanon Hospital Nursing School, New York.

Dr. Herzlin was formerly a member of the medical staff of the Knickerbocker Hospital in New York City.*

• • •

Dr. John R. Ross has resigned as superintendent of Hudson River State Hospital in Poughkeepsie to become superintendent of Rhode Island State Hospital for Mental Diseases at Cranston, Rhode Island.

• • •

Dr. Sydney McLouth, of Corfu, is in Clifton Springs for a three months' residency in surgery at the Clifton Springs Sanitarium.

• • •

Dr. Helen Dollar and Dr. Martin Lazar have been promoted from assistant physicians to senior assistant physicians at the St. Lawrence State Hospital at Watertown.

• • •

Dr. Charles M. Reid, South Jamaica Negro physician, has been appointed associate visiting physician at Queens General Hospital, the first member of his race to hold such a post in Queens General or any other borough hospital.

He is an honor graduate of McGill University Medical College in Canada, having received his degree in 1911. He was first licensed to practice in Virginia, and remained there until 1926, when he came to South Jamaica.

When Queens General Hospital opened in 1935, Dr. Reid was one of five Negro physicians named to the staff. He was made first assistant visiting doctor in 1941 and has now been promoted to the rank of full associate.

He serves as an examining physician for Local Draft Board 274 and is on the advisory committee on Negro health of the Queens Tuberculosis and Health Association.

Dr. Reid helped organize the Jamaica Branch of the National Association for the Advancement of Colored People and served as its president for seven years.

The doctor is married and has a son in the Army.

Newsy Notes

A program designed to solve wartime nursing problems in New York State has been adopted by the New York State Nursing Council, of which Miss Alta E. Dines is chairman.

The plan called for analysis of nursing needs in each community, increase of nursing power, more equitable distribution of community nursing quotas, provision for civilian as well as military nursing needs, increase in student nurses, reactivation of retired graduate nurses, and work with subsidiaries such as Red Cross nurse's aides and other volunteer assistants.

Local nursing councils in the State number 64, against 17 on Jan. 5, it was reported at the meeting. The councils, with lay and professional representation, will study nursing problems in communities.

They will include professional nurses, physicians, hospital administrators, trustees of hospitals, and members of women's organizations and other groups.

Cooperating will be State and local agencies such as health departments, the State Medical Society, the Emergency Medical Service, and other departments of the State War Council.

All officers of the New York State Nursing Council were re-elected yesterday.*

• • •

In the new Army hospital on Staten Island, Halloran General Hospital, war wounded from all areas of battle are being nursed back to health through the skill of the Army Medical Corps. The hospital, originally designed for the mentally deficient children of New York State, comfortably accommodates 3,000 beds and can make room for more than that if necessary.

Under the supervision of Col. Ralph G. Devoe, M.C., the commanding officer, and his staff, the most advanced treatment available is given to the patients.

In addition to regular hospital care, arrangements are made for entertainment and recreation of convalescents. The goal at the hospital is not only to make the wounded well but also to make them self-reliant and happy.

• • •

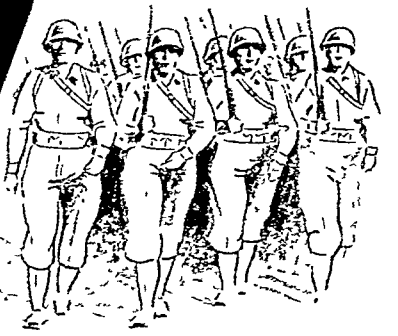
The name of Reception Hospital in Saranac Lake has been changed to Prescott House.

• • •

The nursing schools of Flower-Fifth Avenue, Roosevelt, and St. Luke's Hospitals received citations from the Red Cross on May 26 in recognition of the 100% enrollment of their senior classes in the Red Cross Student Reserve.

• • •

Insurance in the Associated Hospital Service is now available to individual physicians. They need no longer join in groups.



• • •

American transport planes converted into "flying hospitals" after delivering troops and supplies to the front have evacuated more than 30,000 Allied casualties from battle zones in all theaters of the war, Brigadier General David N. W. Grant, air surgeon of the Army Air Forces, revealed at the meeting of the House of Delegates of the American Medical Association in Chicago.*

FIRST AID FOR

V

BURNS

This summer, as never before, physicians will be called upon to treat a large crop of bad sunburn cases and blistered feet (pressure burns).

The civilian as well as the military population will be affected. Office workers and housewives are exposing themselves to the effects of sun and unaccustomed activities—working in victory gardens, replacing the family auto with the use of "shanks' mare."

Effective first aid for these cases is found in

FOILLE

Foille is the modern treatment now so extensively used in military, civilian and hospital practices in the local therapy of 1st, 2nd and 3rd degree burns, wounds and indolent ulcers.

Foille provides quick relief from pain and encourages the healing process.

Wa will gladly send to interested physicians a special complimentary package of Foille in gelatin tubules designed for emergency use in small-area burns. Write for this and full literature.

Distributed through Surgical Supply Houses, Wholesale Druggists, Pharmacists and First Aid Suppliers.

Menace of Typhus in Europe

"From reports at hand it appears that so far American military forces in North Africa have escaped typhus, which is still a menace to the civilian population," the *Journal of the American Medical Association* for June 5 said in an editorial on "The Menace of Typhus in Europe." The *Journal* said:

"Of the communicable diseases that may become epidemic in wartime, typhus is of most concern. In his comprehensive summary of the typhus situation in Europe and North Africa, Yves Biraud of the Epidemiological Intelligence Service Health Section of the League of Nations, points out that typhus is on the increase in the countries of eastern Europe in which the disease usually is endemic, in Spain, and in North Africa, and that it has appeared in sporadic forms in regions of central and western Europe hitherto free from the disease. In eastern Europe typhus is not as widespread as at the end of the first world war. In the West Biraud does not regard the danger of typhus serious 'so long as the population continues on the whole to be free from lice,' but increasing economic disorder and destitution may result in spread of the disease.

"The spread of European typhus, which is the only form of typhus now considered, depends on the presence of the virus and its vector, the body louse, in a receptive population. The special means to prevent the invasion and extension of typhus are delousing and vaccination. In delousing, the people who are most exposed to the infestation come first—vagrants, refugees, the poor—but under certain conditions delousing of military as well as civilian communities may be required.

"Biraud has made a valuable study of the respective advantages and indications of antityphus vaccines, killed and alive. Generally speaking, killed vaccines, which are given in three injections, a week or so apart and which act rather slowly, are best suited for the protection of medical and sanitary personnel and in limited outbreaks in regions where the population in general is stable and free from lice; in other words, when rapid protection is not required. But in outbreaks in shifting and lousy populations, in troops and refugees, live vaccines are best because protection is quickly induced by a single injection. In endemic regions preference should be given, if possible, to vaccines of multiple local strains of the virus; in countries free from typhus but threatened, it would be best to use vaccines of virus from the regions whence the invasion may be anticipated. . . . . With both these methods quantities needed for mass vaccination can be produced and both have given good results in the suppression of epidemics in North Africa. Mass vaccination broke the typhus waves in Morocco in 1937–1938 and in Tunis in 1939–1940. In Tunis, where 200,488 vaccinations were made with the mouse virus, not a single case of vaccinal typhus was observed. Biraud concludes that modern antityphus vaccination coupled with delousing can protect Europe against the present menace of epidemic typhus."—*A.M.A. News*

Home Care of Cancer Patients

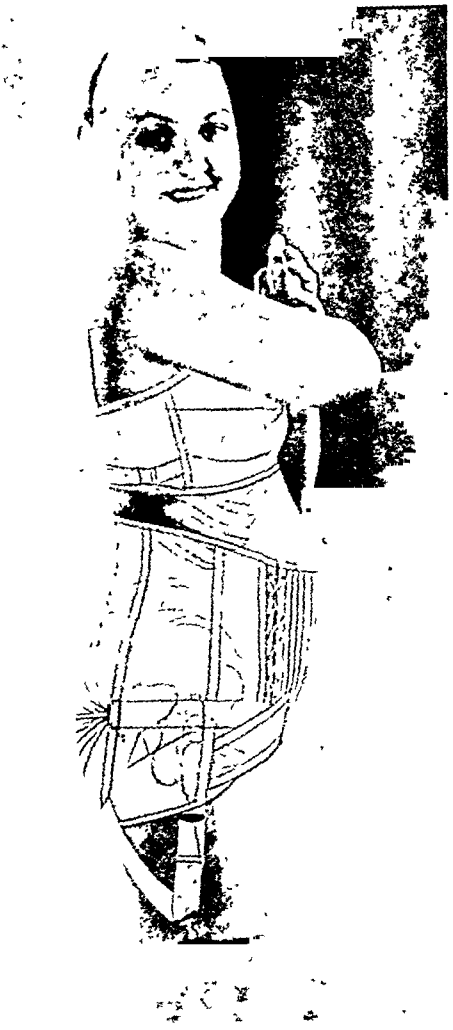
Problems in the home care of cancer patients and some newer methods of meeting them were presented before the staff and guests of the Visiting Nurses Association recently held at Albany.

One of the speakers, Dr. Morton I. Levin, of the Division of Cancer Control, State Department of Health, said that the care of the advanced cancer patient has long been a difficult problem. Hospitals do not want these patients, and there are very few institutions devoted to their care. The situation has been complicated by the war. At the same time, medical science now offers a great deal in the way of measures to decrease pain, alleviate discomfort, treat metastatic lesions, and to add to the lives of such patients months or even years of comfortable existence.

Procedures which have proved efficacious in relieving symptoms of advanced cancer are:

1. Newer methods for control of local infection, such as the use of zinc peroxide dressings or powdered sulfathiazole.
2. Methods for eliminating malodor from lesions.
3. Roentgen therapy for recurrent cancer.
4. Roentgen therapy for metastases to bones or lungs.
5. Neurosurgery and alcohol injections for relief of pain.
6. Castration or the use of estrogenic hormones for treatment of advanced cancer of the prostate.

Many cancer patients do not receive the benefit of such therapy and, in too many cases, not even ordinary nursing care. Dr. Levin said that a complete solution of the problem is not at hand but that it might be met, to some extent, by providing, in the home, nursing procedures and services which for the most part are now available only in hospitals. Supervision by the attending physician would be required in the use of these procedures, but he would be aided if visiting nurses were trained in their application.—*Health News*



Camps for Workers Must Meet Health Requirements

Anticipating an increase in the number of workers moving to farm areas in the State to assist in the production of food, the State Department of Health warned recently that all camps, including those housing farm laborers, must comply with certain provisions of the State Sanitary Code.

The Code requires that each camp operator must apply to the District State Health Officer of his district for a permit at least fifteen days prior to the date of opening a camp. Permits will be issued only after it has been found, following inspection,

[Continued on page 1360]

WARTIME BOOM IN BABIES

Photograph Camp prenatal support (skeleton indrawn)

Today, more babies are on the way than in an time during the last 20 years! Naturally, there i a corresponding rise in the need and deman for prenatal supports.

The S. H. Camp and Company has develope over a period of more than 30 years—*a complet series* of maternity supports . . . each type scien tifically designed and constructed . . . each typ giving accurate support to the abdomen, pelvi girdle and spinal column.

In fact, not a single detail which will add « their clinical value has been neglected.

That these garments successfully measure u to the most stringent clinical requirements i evident—since they carry the approval of man leading gynecologists and obstetricians through out the world.

The Camp series of prenatal supports comprise models suitable for all types of build. Patients are asked to return each month for adjustment of their prenatal supports. This service is given free of charge by all Camp-trained fitters.

CAMP TRADE MARK Supports

[Continued from page 1358]

that each camp meets the requirements of sanitary construction, equipment, and operation.

The department defines a camp as having one or more tents, vehicles, buildings, or structures, including the grounds on which they are located, maintained as living quarters for the temporary occupancy of any number of persons.

Following the filing of an application for a permit, an inspection will be made by a district sanitary engineer. If the requirements in the code are met, a permit for operation will be issued, but if they are not met a permit may be refused or, if changes can be made quickly, recommendations will be made to the camp proprietor for the necessary changes and a temporary permit will be issued. This permit, however, will be valid for only a short period. When the changes have been completed an unqualified permit will be issued. The inspection will include water supply; milk and food sources, storage, and preparation; sewage disposal; sleeping quarters; kitchen; dining room; stable; waste disposal; reporting of sickness; and other items.

Board of Health Amends Sanitary Code

The New York City Board of Health at a recent meeting amended its Sanitary Code, Section 172, requiring that all carcasses of animals to be sold for consumption as meat in New York City bear the Federal imprint or stamp showing the identity of the slaughterer as required by the United States Department of Agriculture.

The action was taken at the request of the Federal Department of Agriculture, as a cooperative step in efforts to wipe out the "black market" sale of meat in the city.

The Board of Health action brings the entire inspectorial force of the Health Department to the aid of the Federal inspectors in checking wholesale meat cuts being brought into New York. It is intended primarily to provide a close watch on meat supplies coming in from small country slaughterhouses which may be shipping in "black market" meat in violation of their Government quotas. At the same time, the new Sanitary Code provision will permit local prosecution of offenders through the City Magistrates' Courts.

Home Deliveries

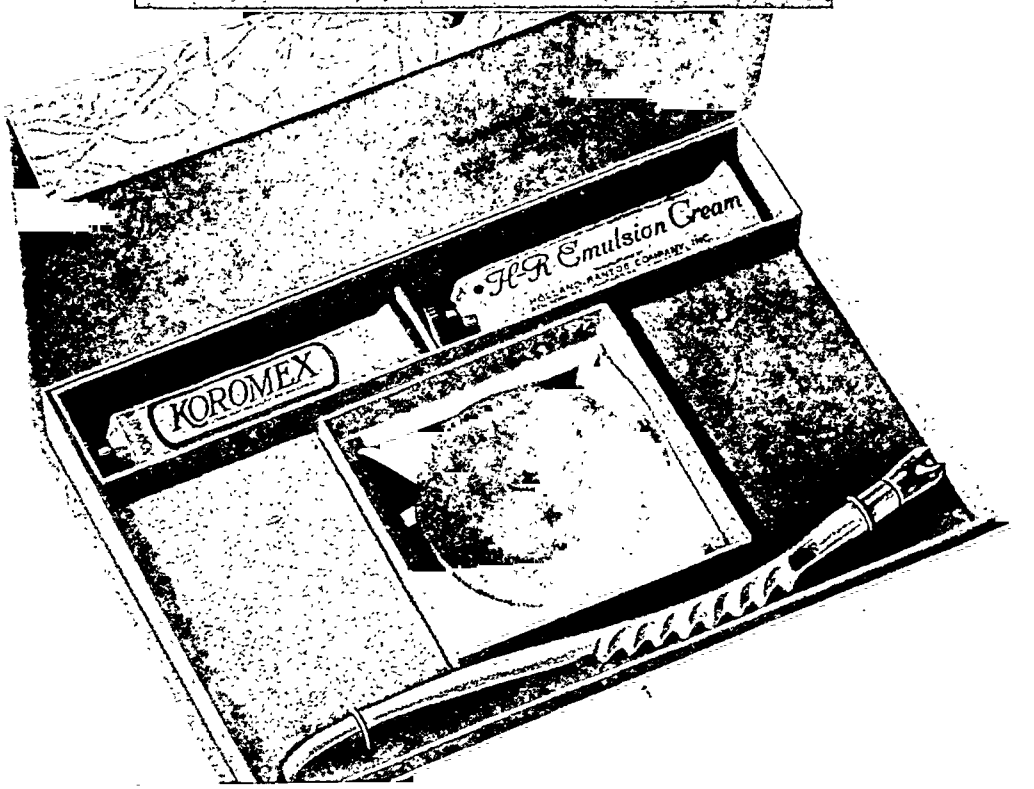
It is obvious that there is now and will be for some time to come a need for delivery service in the home. This should be conducted by trained obstetricians or by properly qualified and supervised nurse midwives.

If in some medical schools home delivery service, in addition to hospital experience, is considered by the authorities of the school to be necessary for the adequate training of medical students in obstetrics, then—

1. The service should be so conducted that the standards for care are on a level with those maintained in the hospital connected with the medical school. In order that the standards may be maintained, there should be:

(*a*) Careful selection of cases for home delivery service, based partly on inspection of the home.
(*b*) Supervision of labor and delivery by members of the obstetric staff.
(*c*) Conduct of labor and delivery with aseptic technic.
(*d*) Qualified nursing assistance at the time of labor and delivery.
(*e*) Qualified medical and nursing care of mother and infant in puerperium.
(*f*) Records of morbidity and mortality among mothers and infants, adequate to demonstrate the results of the service.

2. The area covered by the service should be near enough to a hospital with a specialized obstetric service to provide for hospital care in all emergencies.



How long it will continue to be necessary to train physicians to conduct deliveries in the home is a matter for speculation. Obviously, the ultimate objective of every community should be to have all maternity patients delivered in hospitals maintaining approved standards for the care of maternity patients, by or under the supervision of physicians trained in obstetrics. Only when this is done can all maternity patients and their infants receive the full benefit of the knowledge available concerning the conduct of labor, the puerperium, and the care of newborn infants. Until it is possible to reach this objective, many deliveries will take place in the patient's home, and medical schools must continue to give the best instruction possible on the conduct of home deliveries.—*The Child*

Typhoid Carriers

A total of 437 typhoid carriers, exclusive of those in state institutions, were under supervision in upstate New York at the close of 1942. Thirty new carriers were added to and 25 were removed from the register during the year. Twenty-two were discovered as a result of epidemiologic investigation of sporadic cases of typhoid, 7 by means of release cultures, and one was discovered accidentally while hospitalized with a bronchopleural fistula.

Of the 25 carriers whose names were removed from the register, eighteen died. One was released from restrictions after the submission of the required number of negative fecal and duodenal specimens following cholecystectomy, while the names of 6 others were removed because of change of residence of the carrier to a community outside the jurisdiction of the Department of Health.—*Health News*

A complete unit for Approved Contraceptive Technique

"THE KOROMEX SET COMPLETE"

Koromex Set Complete* is an attractively packaged unit containing the important items used for approved contraceptive technique. Identified by a removable label. To order or prescribe, merely write, "Koromex Set Complete, Diaphragm Size_____".

Each Unit Contains...

KOROMEX DIAPHRAGM—Widely accepted as the outstanding diaphragm in use today. Durable. GUARANTEED FOR 2 YEARS.

KOROMEX TRIP RELEASE INTRODUCER —Specially designed swivel tip facilitates usage. Gauged to take all size diaphragms.

KOROMEX JELLY and H-R EMULSION CREAM—Both preparations have equally high spermicidal value, but differ in degree of lubrication. Both are included so the patient may determine which preparation better meets her requirements and personal preferences.

* *Price of Koromex Set Complete is only that of the Koromex Diaphragm and Koromex Trip Release Introducer*

Familial Nonreagenic Food Allergy. By Arthur F. Coca, M.D. Octavo of 160 pages. Springfield, Ill., Charles C. Thomas, 1943. Cloth, $3.00.

On the basis of recent investigations on food allergies, the writer of this book suggests the addition of another category to the group of allergic diseases. This category has been given the provisional designation, "Familial Nonreaginic Food Allergy." Specific "tachycardia," an increase in the pulse rate of 20 or more, together with a high maximal pulse rate (90 or more), are offered as reliable criteria of the nonreaginic food-allergic reaction, and were employed to identify the offending foods in 44 cases. The allergic symptoms consisted of headaches of various types, physical tiredness, nervousness, indigestion (including gas, vomiting, and nausea), dizziness, neuralgia, canker sores, etc.

Because most of the case reports lack detailed protocols for long periods of time, the allergist is hampered in his attempt to evaluate this method of diagnosis. The internist will find it difficult to interpret the excellent results because the case histories are extremely brief and clinical data are incomplete.

It is maintained that "familial nonreaginic food allergy" affects a large proportion of the population (60 per cent or more). This is in contrast to the low occurrence (7 to 10 per cent) of reaginic atopy.

The relation of "familial nonreaginic food allergy" to various diseases, such as the common cold, hypertension, dementia praecox, and others, is considered.

This book presents a new point of view which should be interesting to the allergist and the internist. The subject merits further study by other workers.

MAX HARTEN

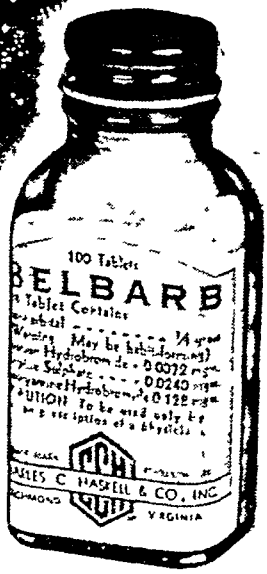
Obstetrical Practice. By Alfred C. Beck, M.D. Third edition. Quarto of 938 pages, illustrated Baltimore, Williams & Wilkins Co., 1942. Cloth, $7.00.

In the third edition of this standard textbook on obstetrics we have a product that surpasses in excellence its two predecessors. It contains some new material, notably in the chapter devoted t pelvic deformity. In the previous editions operativ obstetrics was somewhat condensed in order to b crowded into a single chapter. In this new volume however, a separate chapter has been devoted t each of the following subjects: "Artificial Inter ruption of Pregnancy," "Methods Used to Haste or Complete the Dilatation of the Cervix," "For ceps," "Version," "Cesarean Section," Destructiv Operations," and "Repair of Lacerations."

In the chapter on cesarean section is a clea description, well illustrated, of the method devised by the author for the administration of local anes thesia—one that has proved itself to be most satisfactory. The index has been carefully revised and contains over three times the number of references that were found in the second edition. The book is highly recommended.

W. A. JEWETT

The Principles and Practice of Medicine. Originally written by Sir William Osler. Designed for the use of practitioners and students of medicine. By Henry A. Christian, M.D. Fourteenth edition. Octavo of 1,475 pages. New York, D. Appleton-Century Co., 1942. Cloth, $9.50.



This fourteenth edition is very satisfying. Editor Christian has chosen his new material with good

BELBARB

AN *Excellent*

SEDATIVE and HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg Arch f exp P & P CLX 276) renders possible attainment of desired effects with relatively small doses, thus avoiding hang over and other unpleasant side actions In contrast to galenical preparations of belladonna such as the tincture, Belbarb *has always the same proportion of the alkaloids*

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna

Belbarb No. 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

BRIOSCHI

A PLEASANT ALKALINE DRINK

Actively alkaline. Contains no narcotics, no injurious drugs. Consists of alkali salts, fruit acids, and sugar, and makes a pleasant effervescent drink.

MONTCLAIR, NEW JERSEY

Time to Collect

IT IS NEWS when a collection firm gets fan mail. A doctor writes, "You are wizards." A hospital superintendent says, "Your skillful methods bring checks in every mail." The truth of the matter is that patients who were unable to pay medical fees a few years ago are now receiving fat pay checks. These days there is no such thing as a hopeless account. We are willing to try to collect any of your bills at a moderate percentage of the amount recouped.

Now is the time to write for details.

CRANE DISCOUNT CORPORATION
230 W. 41st St. New York, N. Y.

judgment, and the old is presented with long-established clarity and emphasis.

For the first time bibliographic references are appended. They are pertinent and include articles that appeared as late as 1941 and 1942. To an old reader of Osler, the appearance of the page is admittedly changed by these brief reference paragraphs.

The excellent index is now a commendable feature.

This edition, as is proper, reveals the emphasis and teachings of the fine clinician who is editor. His comments add to the value of the volume, enrich its text, and keep it abreast of all the new information that is accepted and established. The book continues to be the splendid practical guide that it has been since its inception in 1892.

FRANK BETHEL CROSS

Diseases of the Liver, Gallbladder and Bile Ducts. By S. S. Lichtman, M.D. Octavo of 906 pages, illustrated. Philadelphia, Lea & Febiger, 1942. Cloth, $11.

This book is divided into two parts—diseases of the liver and diseases of the gallbladder and biliary passages.

The chapter on the physiology of the liver is well written and concise enough to be of value to the average physician.

The symptomatology of liver disease is discussed fully. The chapter on cirrhosis of the liver should be read carefully for the fund of information to be found there. The special chapter on "Differential Diagnosis and Diagnostic Errors" is especially to be commended. Treatment of specific diseases of the liver is usually considered together with the discussion of the various diseases, but a special chapter on treatment is added in which the author discusses various forms of treatment applicable to most of the liver diseases. The necessity of high protein and high carbohydrate diet and therefore low fat diet is discussed.

The bibliography is extensive and valuable for further study. This book is an important addition to the literature on the liver and its diseases. It should be read by all physicians—general practitioners and specialists alike.

REUBEN FINKELSTEIN

A Handbook of Allergy for Students and Practitioners. By Wyndham B. Blanton, M.D. Octavo of 190 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1942. Cloth, $3.00.

The author offers this book as a condensation of the subject of clinical allergy for the use of the busy student and practitioner of medicine. The text is divided into eight chapters. Anaphylaxis in animals is briefly described. Simple definitions of various terms related to the field of allergy and the method of arriving at a diagnosis of allergic ailments are given. The roles played by inhalants; ingestants, including drugs; injectants; contactants; bacteria; fungi; insects; serum; and physical factors are briefly discussed.

The author proceeds to a description of the various clinical manifestations of allergic diseases such as pollinosis, perennial rhinitis, bronchial asthma, urticaria, angioneurotic edema, atopic dermatitis, contact dermatitis, fungus allergy, and some of the less commonly encountered manifestations of allergy.

This small text is a ready reference for one who seeks an introduction to the subject of clinical allergy. For more detailed instruction concerning the actual handling of allergic cases one of the larger texts would be needed.

MAX GROLNICK

Principles and Practice of Obstetrics. By Joseph B. DeLee, M.D., and J. P. Greenhill, M.D. Eighth edition. Quarto of 1,101 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, $10.

In 1913, Dr. DeLee completed the first edition of his textbook, and since that time he has prepared and revised six other editions. All of them were of the highest standard and they were received with universal acclaim by medical students and practitioners.

Two years ago, Dr. DeLee requested Dr. J. P. Greenhill to prepare a new edition of his monumental book. Happily, DeLee was able to see and approve this new eighth edition before he died.

In this book, many changes have been made. New chapters have been added, a few of which are obstetric and gynecologic endocrinology, the use of vitamin K in obstetrics, fetal erythroblastosis, and roentgenography.

Several chapters have been rewritten, notably those on the toxemias of pregnancy; contracted pelves, from which the old classifications have been omitted and the new ones of Caldwell, Moloy, d'Esopo, and Thoms have been included; and puerperal infection, in which the sulfonamide drugs are discussed.

The changes made are too numerous to mention in this short review. Suffice it to say that the new eighth edition of this monumental textbook remains on the same high plane as the previous editions, and it is one of the outstanding textbooks on present-day obstetric principles and practice.

WM. SIDNEY SMITH

The National Formulary. Seventh Edition. Prepared by the Committee on National Formulary by authority of the American Pharmaceutical Association. Official from November 1, 1942. Octavo of 690 pages. Easton, Pa., Mack Printing Company, 1942. Cloth, $6.00.

The first edition of the *National Formulary*, the official organ of the American Pharmaceutical Association, first appeared in 1888; this Seventh Edition became official November 1, 1942.

Its function is to supply formulas for preparations that are frequently used in the United States but not included in the *United States Pharmacopœia*. It gives standard tests for the identity, quality, and purity of the ingredients used in these formulas.

This edition contains 459 preparation monographs and 273 monographs on drugs and chemicals.

FREDERICK SCHROEDER, JR.

Diseases of the Nose, Throat and Ear. By William Lincoln Ballenger, M.D., and Howard Charles Ballenger, M.D. Eighth edition. Octavo of 975 pages, illustrated. Philadelphia, Lea & Febiger, 1943. Cloth, $12.

Review of this book discloses the important fact that the author and his eminent collaborators mean to keep Ballenger the reliable text that it always has been. Elimination of obsolete data and the extensive addition of new text and illustrations bring this revised edition up to the minute. Rearrangement of the contents and the introduction

For Skins that are "Convalescent"

A skin that is "under-par" can be cleaned and pampered at the same time with CREAM OF SOAP. For this important new product, a colloidal solution of fine soap, is *neutral;* does not alkalize the surface of the skin; does not disturb its normal acid-base balance. But it does clean, even the very greasy skin, thoroughly. Skins that are "convalescent" need CREAM OF SOAP. To find out what it will do for the normal skin, use it yourself! Send a dollar bill for a full sized jar. Address: CREAM OF SOAP, Room 21, 55 West 16th St., New York, 11., N. Y. Your druggist can obtain CREAM OF SOAP from his wholesaler.

Accepted for advertising in publications of the A.M.A. and advertised exclusively to physicians

CREAM OF SOAP, 55 W. 16th St., New York, N.Y

ANOTHER STAFF OF LIFE

Science has just noted that fish juice will maintain life for protracted periods. Clinical tests made on Navy volunteers to see if shipwrecked men in waterless lifeboats can live on fish juice proved they can. After a test of ten days the subjects seemed to be in as good a condition as they were the first day.

The tests were made under the supervision of Dr. Homer W. Smith of the New York University College of Medicine. Credit for the idea belongs to Gifford Pinchot. It was he who pursuaded the Navy to equip lifeboats with fishing tackle; after which, it occurred to him that fish juice might stave off death from thirst. Trying it himself, first, he found it to be without any pronounced fishy taste.

TO BURN UP FAT

Prescribe Lipolysin in obesity to stimulate oxidation process that "burn up" fatty tissue. A dependable endocrine product; *free from dinitrophenol* Tablets—bots 100; Capsules—bots 50, 120, Ampuls—boxes 12. Send for literature, Dept. N, Cavendish Pharmaceutical Corp., 25 West Broadway, New York.

LIPOLYSIN

MALE **FEMALE**

Red Label and Blue Label KARO are Interchangeable in Milk Modification

Both in chemical composition and in caloric value these two types of KARO are practically identical. There is only a difference in flavor.

Either is equally effective in milk modification. Your patients may safely use either type, if the other is temporarily unavailable at their grocers'.

How much KARO for Infant Formulas?

The amount of KARO prescribed is 6 to 8% of the total quantity of milk used in the formula—one ounce of KARO in the newborn's formula is gradually increased to two ounces at six months.

CHECK DEPENDENCY CHECKS

The many reports received recently of service dependency allotment checks being stolen from porches, mail boxes, and other places, have prompted the United States Secret Service to intensify its nation-wide educational campaign.

The following procedure has been urged by the Secret Service as an aid to stopping thieves and forgers of such checks:

1. Be sure some member of the family is at home when checks are due to be delivered.

2. All mail boxes should be equipped with a lock and the individual's name should be printed clearly on the outside of the box.

3. Checks should be cashed in the same place each month, thus making identification easier.

4. Checks should not be endorsed until you are in the presence of the person you will ask to cash it.

To persons and business houses asked to cash government checks, the Secret Service offers this guidance:

1. Insist that a person presenting a government check properly identify himself as the person entitled to the check.

2. Insist that all checks be endorsed in your presence.

3. Require that all checks be initialled by the employees who pay out money for them, or who approve such payment.

Thousands of persons are depending each month on prompt receipt of checks, and every effort is being made by the government to get them out on time and to their rightful destination, but an equal responsibility rests on the payee to insure their safety.

The suggestions made by the Secret Service are in line with one of its constant duties, the protection of currency, coins, and other forms of government obligations—a task which, according to the Service, is magnified in times of war when enemy agents may seek to undermine a nation's financial structure.

[Continued from page 1366]

been prepared as an aid to those doctors in private practice, military service, industrial work, or hospital clinic, who first see and treat the injured hand." He has written a book which splendidly fulfills that purpose. It is complete, not cumbersome, but specific in diagnosis and in directions for treatment. Beginning with the anatomy and followed by the infections of the hand, there is a logical arrangement of the chapters, each sufficient for the guidance of the busy physician or surgeon.

S. Lloyd Fisher

Behind the Sulfa Drugs: A Short History of Chemotherapy. By Iago Galdston, M.D. Duodecimo of 174 pages. New York, D. Appleton-Century Co., 1943. Cloth, $2.00.

Here, again, is a book written for the layman that it would profit a doctor to read with care. He would find it informative and reminiscent. The research worker's trials and tribulations, which resulted in the discovery of the lifesaving group of sulfa drugs, are described. Apparently we have only crossed the threshold of their possibilities. The book is a valuable addition to one's library and a credit to the author.

S. R. Blatteis

Modern Sanitary Engineering for the Use of Architects, Surveyors, Engineers, Medical Officers of Health, Sanitation Officers, Builders, and Students. By G. Eric Mitchell. Octavo of 169 pages, illustrated. Brooklyn, Chemical Publishing Co., 1942. Cloth, $5.00.

This handbook, as stated by the author, has been prepared primarily "for the use of architects, surveyors, engineers, medical officers of health, sanitation officers, builders, and students." One of its virtues lies in its brevity and in the concise, clear form of presentation, which is augmented by numerous simple line drawings. Written by a British sanitarian, the references to legal requirements and standards in that country will not be of maximum value to its American readers. Moreover, it is designed to meet the needs of the individual dwelling rather than to provide a manual that deals with community aspects of the problem.

Thomas D. Dublin

Clinical Diagnosis by Laboratory Methods. By James C. Todd, M.D., and Arthur H. Sanford, M D. Tenth edition. Octavo of 911 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, $6.00.

The tenth edition of *Clinical Diagnosis by Laboratory Methods*, published under the joint authorship of the late James Campbell Todd and Arthur Hawley Sanford, is an admirable and worthy successor to its antecedent editions, the first of which appeared in 1908. The hope, expressed in the preface of this latest presentation, that this edition will meet the needs of teachers, students, medical technologists, and physicians, are sure to be realized.

The book is of such size and weight that it can be comfortably carried. There is an introduction, with an excellent description of the microscope, and detailed instructions for its use. This is followed by 12 chapters of 793 pages of text covering, completely and lucidly, descriptions and explanations of methods in the fields of clinical pathology, clinical chemistry, hematology, bacteriology, cytodiagnosis, serology, parasitology, and the miscellaneous laboratory procedures not falling into special groups. Pathologic (tissue) technic is not included. The illustrations are ample, well placed, and exceptionally clear.

Of the many works in this field which have appeared recently, this easily takes its place in the foremost ranks. It is most heartily recommended to those whose active interests are in any way related to the medical clinical laboratory.

Max Lederer

Orthopedic Subjects. Prepared and Edited by the Subcommittee on Orthopedic Surgery of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. George E. Bennett, Chairman. Octavo of 306 pages, illustrated. Philadelphia, W. B. Saunders Co., 1942.

The title of this volume is somewhat misleading From the title one expects to find information on many orthopaedic subjects, particularly those that would be found as a result of military injuries However, it covers only four subjects: ununited fractures, injuries of the spinal column, compound fractures, and osteomyelitis. In the reviewer's opinion, the last could have been very well left out in a manual of this type, particularly the chapter on acute hematogenous osteomyelitis, as this condition occurs almost entirely in young children.

J. B. L'Episcopo

Essentials of Proctology. By Harry E. Bacon, M.D. Duodecimo of 345 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1943. Cloth, $3.50.

The author designed *Essentials of Proctology* for the medical student, the general practitioner, and the general surgeon. It presents, in condensed form, an exposition of the conditions usually found in the anus, rectum, and sigmoid colon. Diagnosis and hospital as well as office treatment and procedures are emphasized. The work is profusely illustrated.

On the back of the front cover and continued on the fly leaf there is an "Index of Symptoms and Signs" consisting of eleven symptoms and three signs with the presumptive diagnosis following each of them. This index is of value in that its use enables the examiner to suspect the presence of certain lesions. It would be well to emphasize, however, that a diagnosis should never be made without a proper examination. It should further be emphasized that any and all symptoms referable to the anus or rectum may be due to cancer.

The reviewer was very glad to see the chapter entitled "Proctologic Nursing Considerations" included in the book. Modern postoperative care of proctologic patients is sufficiently specialized to require a detailed routine for hospital nurses to follow. This is especially important in these days of shortages.

The book is of such size as to make handling easy and the printing could not be better.

A. W. Martin Marino

Constitution and Disease. Applied Constitutional Pathology. By Julius Bauer, M.D. Octavo of 208 pages. New York, Grune & Stratton, 1942. Cloth, $3.50.

The author has brought with him to America the rich clinical experience that led graduate students to seek him out in Vienna, and now in this small

Of the many works in this field which have appeared recently, this easily takes its place in the foremost ranks. It is most heartily recommended to those whose active interests are in any way related to the medical clinical laboratory.

Max Lederer

Orthopedic Subjects. Prepared and Edited by the Subcommittee on Orthopedic Surgery of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. George E. Bennett, Chairman. Octavo of 306 pages, illustrated. Philadelphia, W. B. Saunders Co., 1942.

The title of this volume is somewhat misleading. From the title one expects to find information on many orthopaedic subjects, particularly those that would be found as a result of military injuries. However, it covers only four subjects: ununited fractures, injuries of the spinal column, compound fractures, and osteomyelitis. In the reviewer's opinion, the last could have been very well left out in a manual of this type, particularly the chapter on acute hematogenous osteomyelitis, as this condition occurs almost entirely in young children.

J. B. L'Episcopo

Essentials of Proctology. By Harry E. Bacon, M.D. Duodecimo of 345 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1943. Cloth, $3.50.

The author designed *Essentials of Proctology* for the medical student, the general practitioner, and the general surgeon. It presents, in condensed form, an exposition of the conditions usually found in the anus, rectum, and sigmoid colon. Diagnosis and hospital as well as office treatment and procedures are emphasized. The work is profusely illustrated.

On the back of the front cover and continued on the fly leaf there is an "Index of Symptoms and Signs" consisting of eleven symptoms and three signs with the presumptive diagnosis following each of them. This index is of value in that its use enables the examiner to suspect the presence of certain lesions. It would be well to emphasize, however, that a diagnosis should never be made without a proper examination. It should further be emphasized that any and all symptoms referable to the anus or rectum may be due to cancer.

The reviewer was very glad to see the chapter entitled "Proctologic Nursing Considerations" included in the book. Modern postoperative care of proctologic patients is sufficiently specialized to require a detailed routine for hospital nurses to follow. This is especially important in these days of shortages.

The book is of such size as to make handling easy and the printing could not be better.

A. W. Martin Marino

Constitution and Disease. Applied Constitutional Pathology. By Julius Bauer, M.D. Octavo of 208 pages. New York, Grune & Stratton, 1942. Cloth, $3.50.

The author has brought with him to America the rich clinical experience that led graduate students to seek him out in Vienna, and now in this small

UNIVERSAL LANGUAGE?

"It is just barely possible—and the idea is turned over timidly to the professors for what it is worth—that there is a basic error in the conception that a world will get along more peacefully if all its people can talk to one another. This conception may be entirely wrong. We have neighbors we have never had a quarrel with and it just happens they are the neighbors we have never spoken a word to. It's the man next door who understands perfectly everything we say that we have trouble with."—*Dooley Dunn, N. Y. Times Magazine*

THE X-RAY TURNTABLE

One of the most recent contributions to aid the diagnostician is an x-ray machine developed by Westinghouse engineers for the University of Pennsylvania Hospital. The machine, with a turntable, enables physicians to change the position of a patient at will during delicate operations to remove foreign bodies from the lungs. Examinations may be made in two planes—horizontally and vertically—and x-ray pictures may be taken from any angle, even vertical, without lifting or turning the patient.

[Continued from page 1368]

volume he discusses individual constitution as it relates to health and disease.

A most interesting and outstanding chapter deals with "Biologic Inferiority of Organs and Tissues."

Classification of types and a discussion of habitus precede a chapter dealing with specific diseases that present a constitutional background. To the clinician this is a banquet.

Broad, sage, continental observations and teachings appear throughout the book, and, in the spirit of medical research and bedside practice, make the volume very much worth while.

FRANK BETHEL CROSS

Acute Infections of the Mediastinum. By Harold Neuhof, M.D., and Edward E. Jemerin, M.D. Octavo of 407 pages, illustrated. Baltimore, Williams & Wilkins Co., 1943. Cloth, $6.00.

The greatest merit of this volume is its originality of presentation, which is based upon the authors' personal experiences in one hundred cases. This does not imply that they have not made themselves fully conversant with the current teachings and literature to which they refer freely. The opening chapter of this volume is devoted to a consideration of the contributions of their predecessors. The second part is a presentation of cases grouped according to cause. From the cases reviewed the authors draw significant conclusions on the causation, symptomatology, clinical manifestations, and management. They discuss the indications for surgical drainage, the approach, and the results thereof. The book is clearly written and presents a practical guide to the surgery of acute infections of the mediastinum. It is a meritorious contribution and is recommended to the notice of the clinician.

LEW A. HOCHBERG

Neurosurgery and Thoracic Surgery. [Military Surgical Manuals, Vol. VI.] Prepared and Edited by the Subcommittees on Neurosurgery and Thoracic Surgery of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. Octavo of 310 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, $2.50.

This book is Volume 6 of the "Military Surgical Manuals." It contains a preliminary chapter on the treatment of gunshot and other head injuries, which covers the subject adequately and, at the same time, presents it in a manner that will be helpful to the general surgeon who is faced on the field of battle with the necessity of dealing with a branch of surgery which in civilian practice is now handled by specialists. The points of emphasis are still, as they were twenty-five years ago, on the importance of operating on severe head injuries within the first twelve hours after the injury occurs, but, at the same time, not undertaking this operation except in a place where the equipment is adequate and where the patient can spend at least part of his convalescence. Furthermore, the tremendous importance of the sulfonamide drugs is adequately indicated.

The section on spinal cord injuries is judicious and discusses the important problems of how to avoid increase of injury to the nervous structures within the fractured spine and of operative and non-operative intervention.

An excellent presentation of the subject of herniated nucleus pulposus is also given briefly. Then follows a detailed chapter on peripheral nerve injuries, which contains not only instructions as to how to handle injuries of the peripheral nervous system but, what is equally as important, how not to handle these injuries. There are valuable charts for the examination of peripheral nerves.

The final section of the volume is an excellent presentation on war surgery of the chest.

LEO M. DAVIDOFF

Extra-Mural Teaching of Preventive Medicine and Public Health. The Medical Bulletin of the University of Cincinnati, Volume IX. By Alfred Korach, M.D. Quarto of 143 pages. Cincinnati, University of Cincinnati, 1942.

Presenting one phase of the teaching of preventive medicine developed at the University of Cincinnati College of Medicine, this volume deals with methods of introducing the student to those community health resources which assist and supplement the efforts of the private practitioner in the treatment and prevention of disease. Written primarily for the benefit of medical educators, it should prove of interest to the graduate physician also in keeping him abreast of some current trends in undergraduate medical instruction.

THOMAS D. DUBLIN

The Inner Ear. By Joseph Fischer, M.D., and Louis E. Wolfson, M.D. Octavo of 421 pages, illustrated. New York, Grune & Stratton, Inc., 1943. Cloth, $5.75.

This is a thorough compilation of the more recent available data on the internal ear, its anatomy and pathology, gross and microscopic. The controversial subject of physiology and neurotology is exhaustively presented and to a degree clarified. Little attempt is made to evaluate the numerous theories underlying known reactions to stimulation of the labyrinth. The text covers localization of central lesions, traumatic and spontaneous. The book is timely in that one of the authors discusses in detail war injuries, based on extensive observations during the air blitz on London. A chapter is devoted to the debatable Ménière's syndome and another to the important subject of the inner ear in aeronautics.

Repetition of subject-matter in many chapters is unavoidable and, in fact, desirable.

Slight confusion is inevitable unless one is acquainted with European nomenclature as it is applied to anatomy and physiology of the internal ear.

Editing of this work represents a labor of love and the authors are to be congratulated for their efficiency.

This volume is recommended for individuals concerned with traumatic surgery, neurology, and neurosurgery as well as for those interested in advanced otology and aviation medicine.

HARRY MEYERSBURG

Understand Your Ulcer. By Burrill B. Crohn, M.D. Octavo of 199 pages, illustrated. New York, Sheridan House, 1943. Cloth, $2.50.

Unfortunately this well-written book by a famous author shows the usual faults connected with a medical book written for laymen. Attempting to clarify a subject which is still one of the most controversial issues in medicine, it would satisfy the patient under the author's care, but would alien-

ate the patient who is being treated by a physician whose opinions might differ quite radically from those expressed by the author. On the whole, we believe that although a layman would be much interested in this book, he would be more confused than helped by it.

A. F. R. ANDRESEN

First Aid to the Injured and Sick. An Advanced Ambulance Handbook. Edited by Norman Hammer, M.R.C.S. Eighteenth edition. Duodecimo of 336 pages, illustrated. Baltimore, Williams & Wilkins Co., 1942. Cloth, $2.00.

This is a well-written and excellently illustrated text on first aid. It is a few steps in advance of the Red Cross volume used in this country.

The first quarter of the work (90 out of more than 300 pages) is devoted to anatomy and physiology that is, we believe, a bit too detailed and too deep for use by first-aiders.

The illustrations throughout are most lucid and very instructive. They are quite numerous as well.

The section on war gases is well presented and comprehensive.

The whole volume reflects the first-hand experience that the British people have had with this broad problem.

The book is highly recommended for advance students in first aid.

PHILLIP E. LEAR

Neurology. By Roy Grinker, M.D. Third edition. Octavo of 1,136 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1943. Cloth, $6.50.

In this third edition, the author has incorporated the various contributions made to the field of neurology since the publication of the last edition. He was assisted by Dr. Norman A. Levy. The book is an exhaustive survey of the subject and truly encyclopedic in its scope. Embryology, neuroanatomy, neurophysiology, and neuropathology are discussed, in addition to the usual orthodox presentation of clinical neurology and methods of treatment. The chapter on brain tumors, written by Dr. Paul C. Bucy, is a thorough presentation of neurology that will appeal to the student, the clinician, and the specialist. It is highly recommended to all practitioners of medicine.

IRVING J. SANDS

The Kenny Concept of Infantile Paralysis and Its Treatment. By John F. Pohl, M.D. Octavo of 366 pages, illustrated. St. Paul, Minn., Bruce Publishing Co., 1943. Cloth, $5.00.

This is the latest and most authoritative book on the Kenny treatment. It is an honest and unbiased statement of facts as observed by Drs. John F. Pohl, Frank R. Ober, and Miland E. Knapp. These men have watched the work under direct supervision of Sister Elizabeth Kenny, and the conclusions drawn by these observers are impartial, convincing, and most encouraging.

Causation, pathology, and other debatable questions of poliomyelitis are not to be found in this work. Here one finds a detailed discussion of the method and mode of treatment of infantile paralysis in accordance with the concept of Sister Elizabeth Kenny as it is being applied at the Elizabeth Kenny Institute in Minneapolis, under direct supervision of Sister Kenny. Very helpful will be the many photographs in chapters 3 and 4, dealing with nursing care and muscle spasm.

HARRY APFEL

A Venture in Public Health Integration. The 1941 Health Education Conference of the New York Academy of Medicine. Octavo of 56 pages. New York, Columbia University Press, 1942 Cloth, $1.00.

Rarely does a physician have the opportunity to review in as brief a form some of the burning questions of present-day medical practice. In 56 brief pages, three eminent health educators have stated clearly what they believe to be some of the fundamental issues facing those engaged in meeting the medical needs of the community. Constructive suggestions are also made as to how health education, in which the private practitioner must play a leading role, may help in solving many of the problems.

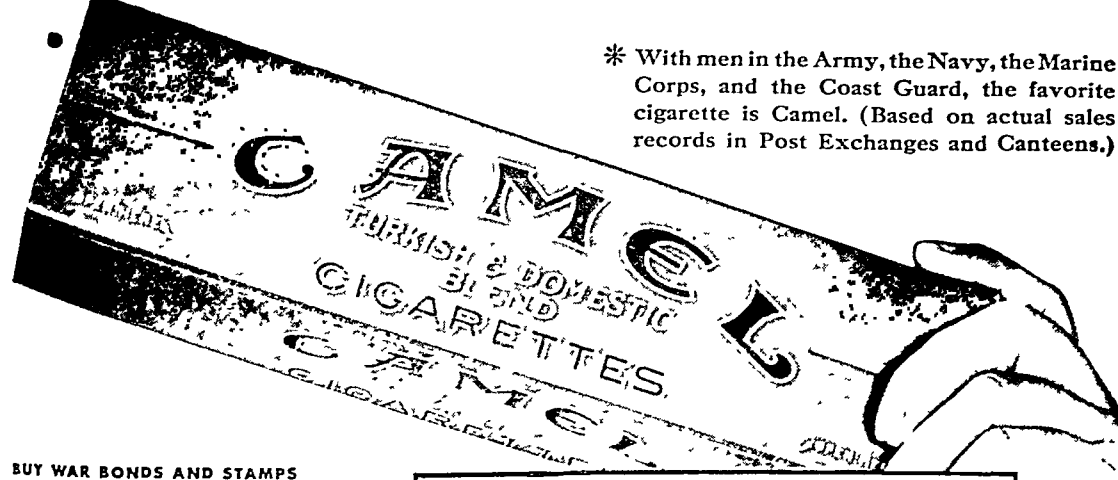
Upjohn Diethylstilbestrol Perles

for easy control of dosage



Rapid relief from vasomotor and mental symptoms of the menopause depends on careful control of dosage. With Upjohn Diethylstilbestrol Perles this dosage control is easy, flexible. For oral use there are now four Perles in different strengths from which to choose. Each Perle is color-coded. It bears a bright, quickly-identified color which helps the physician and the dispensing pharmacist to recognize the potency—light green, 0.1 mg.; green, 0.25 mg.; blue-green, 0.5 mg.; blue, 1.0 mg.

Upjohn Diethylstilbestrol Perles are indicated wherever an estrogenic effect is desired. They have been found of particular value, not only during the menopause, but in senile vaginitis, in gonorrheal vaginitis, and in relieving or preventing painful engorgement of the breasts during suppression of lactation.

Upjohn Diethylstilbestrol Perles are available in each of the four potencies in bottles of 100 and 500

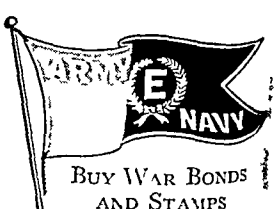
RHULITOL

Lederle

Formula Tannic Acid 6% in a solution containing glycerin, chloro butanol (chloroform derivative), 1%, phenol, 0.4%, camphor, ammonium alum; isopropyl alcohol, 38% (v/v), and distilled water.

PACKAGES

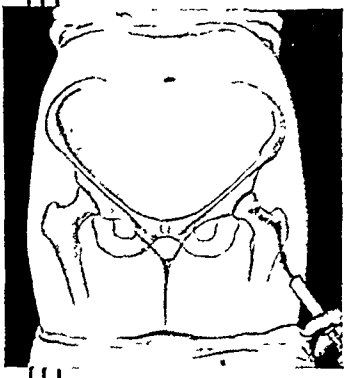
4 fl oz, bottle



RHULITOL—a solution of tannic acid—exerts a protein coagulating effect upon the superficial lesions of contact dermatitis that tends not only to allay some of the local inflammatory signs but also to prevent extension of the dermatitis by dissemination of the toxic principle.

PUBLIC HEALTH OFFICERS should make every effort, during the season of poison ivy, poison oak and sumac, to encourage measures which will minimize or prevent contact dermatitis with its attendant disability and absence from useful occupations. In the case of children, their disability may be shortened and their need for care lessened by appropriate treatment.

"RHULITOL, *Lederle*" is recommended for the local treatment of acute contact dermatitis caused by poison ivy, poison oak and sumac



Literature will be sent on request

TECHNIC OF LIPIODOL INSTILLATION

VISUALIZATION OF *Sinus and Fistula Tracts*

THE instillation of Lipiodol—iodized poppyseed oil containing 40 per cent iodine in chemical combination—into sinus and fistula tracts provides an accurate means of outlining the extent, nature, and tortuosity of these cavities. Lipiodol (warmed to body temperature) is introduced directly into the external opening by means of a drainage tube if present, or an acorn tip attached to the syringe. After the injection the opening of the tract is closed with adhesive tape in order to prevent escape of the oil while roentgenograms are being taken.

THE above procedure is applicable in the roentgen exploration of virtually any sinus or fistula tract. Fistula-in-ano, empyema cavities, persistent, draining sinuses, tracts leading into joints, and other soft tissue wounds which appear to be channels and whose distal ends have not been accurately located, are all promptly visualized by the instillation of Lipiodol.

Physicians are invited to request the brochure "The Applicability of Lipiodol in Roentgenography and the Technic of its Use," which describes in detail the many uses of Lipiodol.

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna.

Belbarb No. 2 *has the same alkaloidal content but* ½ grain phenobarbital per tablet.

"PRE-TEST"
VAGINAL INFECTIONS

In many cases you can clear up a vaginal condition with a single prescription of STA-O-GEN Vag-I-Caps.* In any case, a box of 12 is ample for a 2-week "pre-test" period, to determine the severity of the infection. As you know, STA-O-GEN's prolonged, continuous liberation of nascent oxygen is harmless yet powerfully germicidal, fungicidal and deodorizing. The symptomatic effects annoying your patient are relieved immediately — odor is eliminated—discharge reduced and irritation soothed. If, after this "pre-test" therapy, trouble persists, you can be certain the case will warrant the time and effort required for a comprehensive diagnosis; while your examination and treatment will be less of an ordeal.

* Ozonide of Olive Oil in 45 minim soluble gelatin capsules. David Nye Barrows, N. Y. State Jr. Med. Vol. 41, Jan. 15, 1941.

STA-O-GEN Liquid for office and Vag-I-Caps for home use are available through any wholesaler or direct from

ERTRON*

LABORATORIES, CHICAGO

A PROGRAM OF REHABILITATION

IN PLANNING an outline of treatment for the patient with chronic arthritis, the systemic nature of the disease should be given full consideration.

Ertronization is a systemic therapy. The gradual, steady improvement obtained with ERTRON indicates its systemic action.

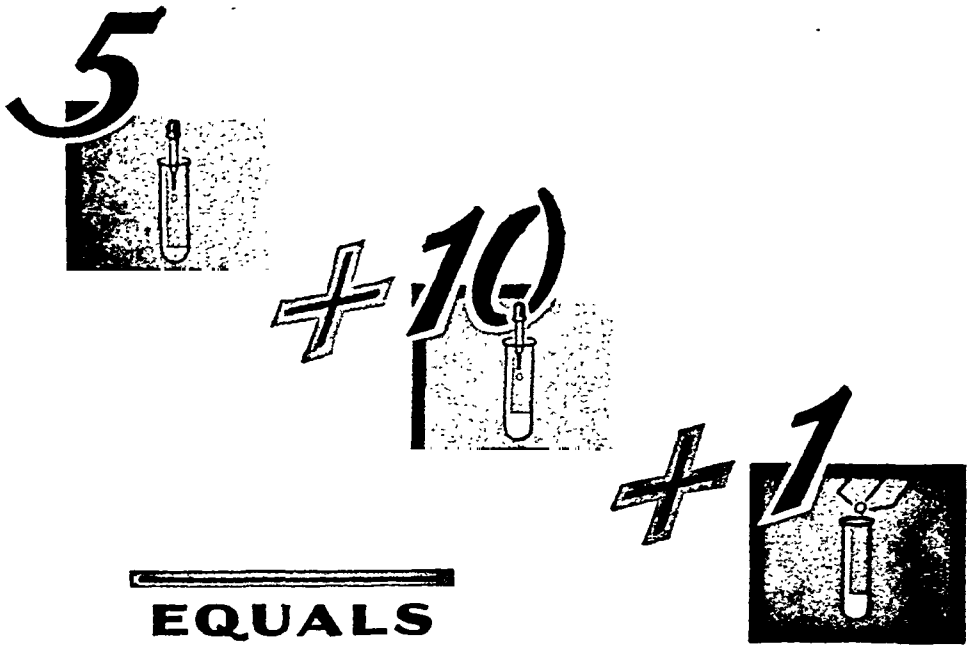
It is generally agreed that analgesic medication may often be indicated during the course of *Ertronization*, and physical therapy measures may be employed to advantage. The removal of foci and the regulation of diet are also important.

In most of the investigations on the use of ERTRON in the treatment of chronic arthritis, no forms of therapy other than *Ertronization* were employed. This was done in order to demonstrate the true value of ERTRON in arthritis.

However, in a well-planned program of rehabilitation based on *Ertronization*, a complete co-ordination of therapeutic measures is necessary for best and quickest results.

Ertronize the Arthritic

ERTRON is the only high potency, activated, vaporized ergosterol (Whittier Process)—made only in the distinctive two-color gelatin capsule.



Average maintenance dose: 6 capsules a day. Full outline of suggested dosage available on request.

Supplied in bottles of 100 and 50 capsules.

ERTRON is promoted only through the medical profession.

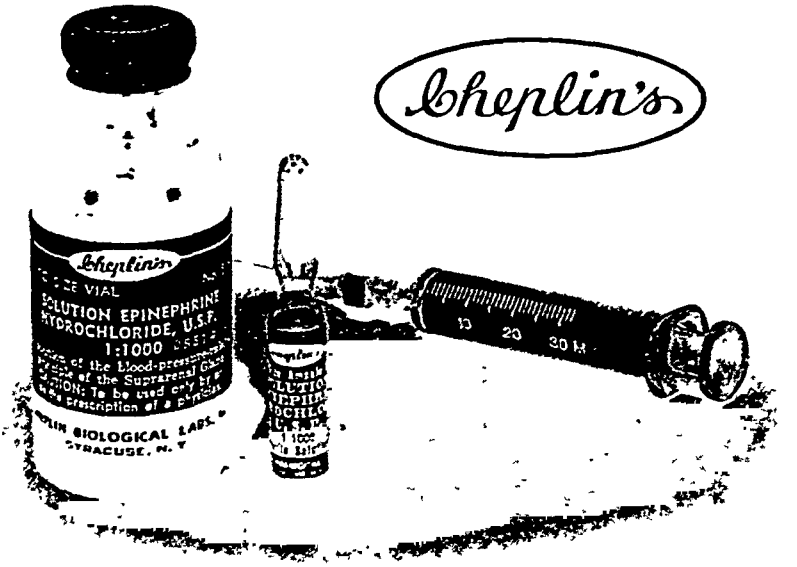
FOR GASTROINTESTINAL DISORDERS
Tablets ALMUTAL No. 1

ANTACID • ADSORBENT • ANTISPASMODIC



A balanced antacid formula for controlling gastric hyperacidity and eliminating intestinal toxemia; suggested in the treatment of spasm of the pylorus and the intestines, toxic bowel, colitis, nervous insomnia and nervous indigestion. Write for samples and literature.

MUTUAL PHARMACAL COMPANY
INCORPORATED
821 S. STATE ST. SYRACUSE, N. Y.

Each Tablet Contains:
Magnesium Trisilicate, Hydrated . . . . . 5 gr.
Aluminum Hydroxide . . . . . 2 1/2 gr.
Phenobarbital . . . . . 1/8 gr.
Atropine Sulfate . . . . . 1/1000 gr.

Tablets Almutal No 1 are orange colored and orange flavored.

Price: **$2.70 per 1000** list

Epinephrine Hydrochloride 1:1000 N.N.R.

CHEPLIN'S solution of this powerful vasoconstrictor, hemostatic and circulatory stimulant is adjusted to a definite standard strength and is physiologically assayed by measuring the effect on blood pressure.

EPINEPHRINE HYDROCHLORIDE may be administered by hypodermic, inhalation or topical application, affording rapid relief of asthmatic symptoms, urticaria, angioneurotic edema, reactions following injections of biologicals, shock or collapse, and prompt control of certain types of hemorrhage. When used in conjunction with topical, nerve block or infiltration anesthesias, it produces a bloodless operative field and retards absorption of the anesthetic—thus prolonging the period of anesthesia. Literature on Request.

EPINEPHRINE HYDROCHLORIDE is packaged as 1:1000 in:

1 cc. ampules.
10 cc. rubber-stoppered vials.
30 cc. rubber-stoppered vials.
30 & 480 cc. bottles for topical applications.

THESODAN
The ORIGINAL ENTERIC-COATED TABLET OF THEOBROMINE SODIUM ACETATE
Brewer
EFFECTIVE
*in Coronary Artery Disease and Edema**

Clinical experience and carefully controlled studies in *humans* have definitely proven the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal diseases, and the value of the enteric coating in permitting adequate dosage without causing gastric distress.

Supplied—in 7½ grains with and without Phenobarbital ½ grain; in 5 grains with Potassium Iodide 2 grains and Phenobarbital ¼ grain (cost approximately $1.50 per bottle of 100 tablets); and in 3¾ grains with and without Phenobarbital ¼ grain (cost approximately $1.00 per bottle of 100). Capsules, not enteric coated, are available in the same potencies for supplementary medication.

*Literature giving confirming bibliography, and physicians samples will be furnished on request

BREWER & COMPANY, INC. Worcester Massachusetts
Pharmaceutical Chemists Since 1852

PROLONGED VASCULAR RELAXATION WITH NITRANITOL

Brand of Mannitol Hexanitrate

in Hypertension

Due to the chronicity of hypertension, the object of medical treatment is to produce gradual and prolonged vasodilation, with a resultant steady lowering of the systolic and diastolic pressures.

A non-toxic nitrate derivative which meets the requirements of gradual, extended action is mannitol hexanitrate, available for clinical use under the name of Nitranitol.

The prolonged vasodilating action of mannitol hexanitrate as compared with other hypotensors is best shown by the following table based on results of the work of Matthew, as summarized by Sollman. (Manual of Pharmacology, Philadelphia, W. B. Saunders & Co., 1942, p. 518)

DRUG	DOSAGE	EXTENT OF FALL (in mm. Hg pressure)	REACHING AND RETURNING FROM MAXIMAL FALL ▭ MAXIMAL FALL MAINTAINED ▬
Spir glyceryl nitratis	2-3 mins	25 - 30	
Sodium nitrite	2 3 grs	32	
Erythrityl tetranitrate	½ 1 gr	35	
Mannitol hexanitrate	1 gr	35	
			Hours 1 2 3 4 5 6 7 8 9 10 11 12 13

Nitranitol is prepared in the form of scored tablets, each containing ½ gr. mannitol hexanitrate. Average dosage is one or two tablets every 4 to 6 hours. Available at prescription pharmacies in bottles of 100.

NITRANITOL WITH PHENOBARBITAL

A combination product containing ½ gr. mannitol hexanitrate and ¼ gr. phenobarbital. Scored tablets in bottles of 100.

Adequate Nutrition,

RATIONING, FOOD AVAILABILITY

As civilian food supplies dwindle because of the increased requirements of our armed forces and allies, the spectre of widespread malnutrition looms more vividly. Yet the nutritional state of our population must be maintained at a high level because of its effect upon morale, resistance to disease, and productivity.

New Improved Ovaltine offers a ready means to overcome the adverse influence of curtailed food availability. The well-rounded composition of this delicious food drink assures an adequate intake of virtually all essential nutrients—not only vitamins, but also biologically adequate proteins and minerals. From the analyses reproduced below, it becomes apparent that the average diet, plus two or three glasses of Ovaltine daily, will adequately satisfy all nutritional needs. . . . The Wander Company, 360 North Michigan Avenue, Chicago, Illinois.

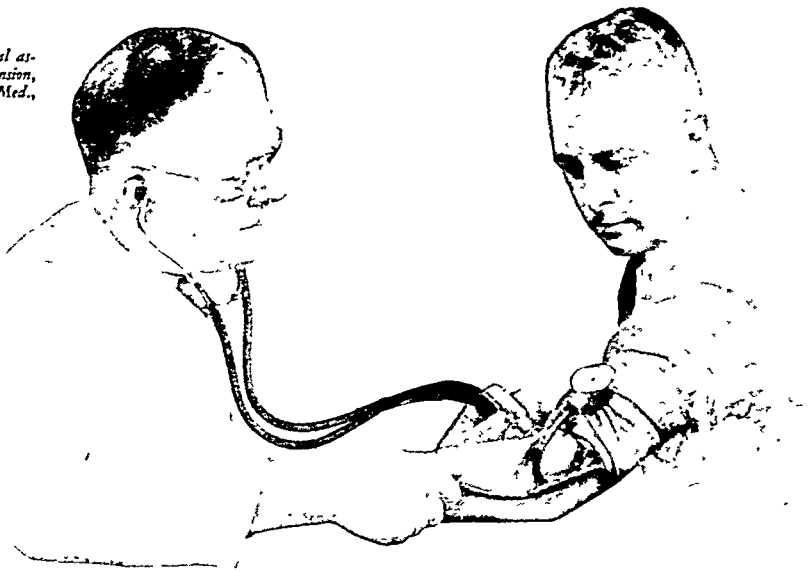
2 KINDS
PLAIN AND CHOCOLATE
FLAVORED

NEW IMPROVED
Ovaltine

Three daily servings (1½ oz.) of New Improved Ovaltine provide:

	Dry Ovaltine	Ovaltine with milk*		Dry Ovaltine	Ovaltine with milk*
PROTEIN . . .	6.00 Gm.	31.20 Gm.	COPPER	0 5 mg.	0.5 mg.
CARBOHYDRATE	30.00 Gm.	66.00 Gm.	VITAMIN A .	1500 U.S.P.U.	2953 U.S.P.U.
FAT	3.15 Gm.	31.5 Gm.	VITAMIN D .	405 U.S.P.U.	432 U.S.P.U.
CALCIUM . . .	0 25 Gm.	1.05 Gm.	VITAMIN B_1	300 U.S P.U.	432 U.S.P.U.
PHOSPHORUS .	0.25 Gm.	0.903 Gm.	RIBOFLAVIN .	0 25 mg.	1.28 mg.
IRON	10.5 mg.	11.9 mg.	NIACIN	4.95 mg.	7.1 mg.

*Each serving made with 8 oz. milk; based on average reported values for milk.



THE IMPORTANCE OF HYPERTENSION

"The importance of hypertension as a problem of health needs emphasis. High blood pressure is both a common disease and a serious one. Indeed, it appears to be more common and more deadly than cancer."*

"About a fourth of all deaths of individuals past fifty years of age is referable to hypertension."*

". . . hypertension usually is a serious disease which terminates the lives of those it afflicts within a relatively short period."*

*Allen, E. V., *Medical aspects of arterial hypertension*, *Bull. N. Y. Acad. Med.*, 17: March, 1941.

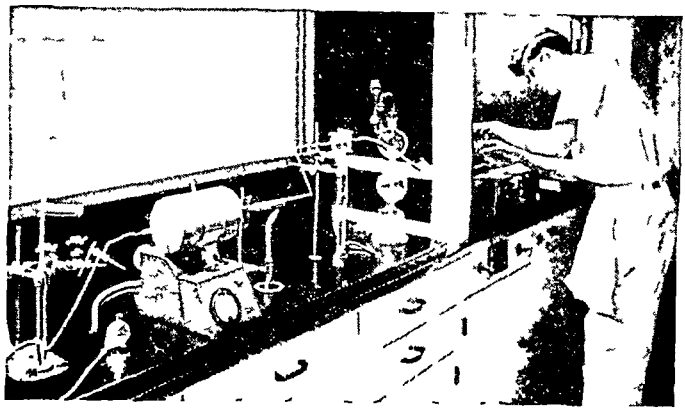
PROLONGED REDUCTION OF HIGH BLOOD PRESSURE WITH ERYTHROL TETRANITRATE MERCK

TREATMENT of arterial hypertension today is necessarily directed toward relief and not cure. The use of Erythrol Tetranitrate is suggested as an additional measure when the usual regimen of rest and dietary control has proved inadequate.

Erythrol Tetranitrate offers the advantage of producing such a prolonged reduction in blood pressure that administration three times daily may be adequate to maintain the desired level. It may be prescribed over an extended period with sustained effect.

The vasodilator action of Erythrol Tetranitrate usually begins about fifteen minutes after administration and persists for a period of three to four hours. The average dose is ½ to 1 grain (0.03 to 0.06 Gm.) every 4 to 6 hours, in tablets as marketed.

ERYTHROL TETRANITRATE MERCK
(Erythrityl Tetranitrate)



For Prolonged Vasodilatation in Hypertension

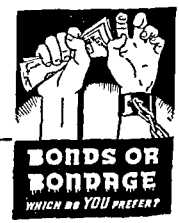
SEARLE RESEARCH

Micro analytical Apparatus for the Determination of the Precise Chemical Composition of Material

Brought

FLORAQUIN

TO YOUR ARMAMENTARIUM



The efficient (restorative) treatment for vaginal leukorrheas as provided in Floraquin was developed in the Searle Research Laboratories after years of painstaking research.

In the many forms of vaginal infection, Floraquin affords permanent and lasting relief, without reinfection.

Floraquin not only destroys Trichomonas vaginalis and other offending organisms, but restores mucosal glycogen and the vaginal pH to a physiologic level and promotes growth of the normal bacterial flora.

For Office Insufflation Floraquin Powder. Bottles of 1 oz. and 8 oz.

For Home Routine Floraquin Tablets Boxes of 24 tablets

RESEARCH IN THE SERVICE OF MEDICINE

THREE NUTRITIONAL ESSENTIALS
FOR THE GROWING CHILD

"At least 3 nutritional essentials deserve special emphasis in childhood, viz., *vitamin D, protein* and *calcium.*

"Vitamin D is required throughout the growth period, a fact extensively overlooked. Milk, as our only constant good food source of calcium, is not taken in sufficient quantity by a large number of children.

"Protein deficiency is much more common than is generally realized.

"A diet adequate in protein cannot be arranged fortuitously without the addition of milk."*

All of these basic food requirements are supplied in pleasant-tasting, easily digested Horlick's Fortified {full cream milk, malted barley and wheat nutrients, added maintenance doses of A, B_1, D and more than 50% of G}.

NOTE: Horlick's is delicious whether prepared with milk *or with water.*

Also ideal for between-meals' feeding — Horlick's Tablets — available in conveniently carried {25¢} oval flasks.

* Jeans, P.C.: Feeding of Healthy Children, J.A.M.A., {Nov. 21} 1942, p. 921.

Estivin

ONE DROP IN EACH EYE BRINGS HAY FEVER RELIEF

The distressing ocular and nasal symptoms of hay fever usually respond promptly to the administration of Estivin. Itching eyes, lacrimation, uncontrollable sneezing and associated discomforts of the eyes and nose are usually relieved upon the first application.

One drop of Estivin in each eye, two or three times daily is generally sufficient to keep the average patient comfortable during the entire season. In more severe cases, additional applications whenever the symptoms recur will keep such patients relieved throughout the day.

THE FIRST PAIR OF SHOES

Some early human being, and he might have been one of the Homo neanderthalensis or a Homo sapien, probably found that some bark of trees tied to the soles of the feet with thongs of vine, helped him to move faster and easier over stony ground. So the first pair of shoes may have been conceived.

But we must all have our first pair of shoes—an ordeal that many parents have not enjoyed because it seems we are all born to rebel against "pressure." While Pediforme service may not actually supply the first footwear, it has on countless occasions been called upon to "save the situation" when trouble does begin even in the youngest members of the family. You don't have to wait for the octogenarian patient before prescribing a helpful pair of Pediforme shoes.

"a clinically proven formula and therapy..."

LUASMIN
Brewer

Theophylline Sodium Acetate 3 grains
Ephedrine Sulphate..... ½ grain
Phenobarbital Sodium..... ½ grain

for BRONCHIAL ASTHMA, HAY FEVER, URTICARIA.

Supplied: Capsules for prompt and symptomatic relief. Tablets, enteric-coated, for delayed action and prophylactic relief.

Therapy: One capsule and one tablet at bedtime. The capsule provides 4 or more hours of relief beginning in fifteen or twenty minutes—the enteric-coated tablet begins giving relief 3½ to five hours later for another 4 or more hours, thus assuring a full night of uninterrupted sleep.

Substantiation: Reports in medical journals and books confirm the value and usefulness of Ephedrine, Phenobarbital and Theophylline in the treatment of Asthma and other allergic conditions by oral administration. Our literature on LUASMIN reviews the conclusions arrived at by medical authorities.

Samples and literature on request

Editorial

Political Medicine

A bill proposing to create a Unified National Social Insurance System (*S. 1161; H.R. 2861*) was introduced in the Senate by Senator Wagner, of New York, for himself and Senator Murray, of Montana, and in the House by Representative Dingall, of Michigan, on June 3, 1943.

"*Senate Bill 1161* makes provision for *free* general medical, special medical, laboratory, and hospitalization benefits for more than one hundred ten million people in the United States.

"It proposes placing in the hands of one man—the Surgeon General of the Public Health Service—the power and authority:

1. To hire doctors and establish rates of pay—possibly for all doctors;
2. To establish fee schedules for services;
3. To establish qualifications for specialists;
4. To determine the number of individuals for whom any physician may provide service;
5. To determine arbitrarily what hospitals or clinics may provide service for patients.

"The provisions are so sweeping that, if enacted into law, the entire system of American medical care would be destroyed. . . .in the opinion of some.

"In its evolution the Wagner-Murray-Dingall bill stems from the National Health Conference of 1937, the Wagner bill which followed that conference, and the report of the National Resources Planning Board. Essentially in its medical aspects it is a compulsory sickness insurance bill and an attempt to translate the proposals of the Social Security Board into a technic of action. Inquiry of reliable sources in Washington indicates the probability that the actual designers and authors of the bill included I. S. Falk, director of the Bureau of Research and Statistics of the Social Security Board of the Federal Security Administration, Mr. Wilbur J. Cohen, technical adviser to the Social Security Board, and Senator Wagner's secretary, Mr. Philip Levy. A statement issued by William Green, president of the American Federation of Labor, says. 'The measure, which is the most comprehensive attempt yet made to establish postwar security in this country, is the fruit of a five-year study of experts on the staff of the American Federation of Labor, which will give the proposed program full sponsorship and support.'"[1]

The powers conferred by this bill on the Surgeon General of the Public Health Service are summarized by the *J.A.M.A.* in part, as follows:

"The Surgeon General of the Public Health Service is hereby authorized and directed to take all necessary and practical steps to arrange for the availability of the benefits provided under this title. . . . .

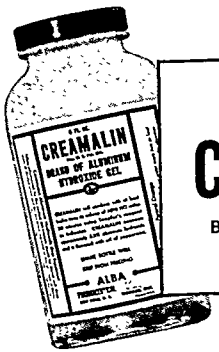
". . . . The Surgeon General is hereby authorized to negotiate and periodically to renegotiate agreements or cooperative working arrangements with appropriate agencies of the United States, or of any state or political subdivisions thereof, and with other appropriate public agencies, and with private persons or groups of persons, to utilize their services and facilities and to pay fair, reasonable, and equitable compensation for such services or facilities. . . . .

"There is hereby established a National Advisory Medical and Hospital Council to consist of the Surgeon General as Chairman and sixteen members to be appointed by the Surgeon General.

"The Surgeon General shall publish and otherwise make known in each area to individuals entitled to benefit under this title the names of general practitioners who have agreed to furnish services. . . . .

"Services which shall be deemed to be specialist services shall be those so designated by the Surgeon General, and the practitioners from among those included in paragraph 1 above who shall be qualified as specialists and entitled to the compensation provided for specialists shall be those so designated by him as qualify to furnish such specialist services. . . . .

THE RISING CURVE OF PEPTIC ULCER IN WAR



"Peptic Ulcer ranks high as a cause of disability for military service. It . . . leads all other digestive diseases as a cause for discharge from the Regular Army."

Kantor, J. L.: Digestive Disease and Military Service, Jnl. A. M. A., Sept. 26, 1942.

THE increased incidence of peptic ulcer among the armed forces, defense workers and civilians today confronts medicine as a major problem.

Of the various types of therapy used to control this problem none has proved itself more valuable than CREAMALIN, brand of aluminum hydroxide gel.

CREAMALIN, the first aluminum hydroxide gel to be made available to physicians, was also the first to be Council-accepted. CREAMALIN contains approximately 5.5% aluminum hydroxide.

ACCEPTED
AMERICAN MEDICAL ASSN.
Council on Pharmacy and Chemistry

CREAMALIN
REG. U. S. PAT. OFF.
Brand of Aluminum Hydroxide Gel

Therapeutic Effects of CREAMALIN

- Pronounced antacid action of 12 times its volume of N/10 HCl in less than 30 minutes (Toepfer's reagent)
- Prolonged action in contrast to fleeting effect of alkalies
- Non-alkaline; non-absorbable; non-toxic
- No acid rebound; no danger of alkalosis
- Prompt and continuous pain relief in uncomplicated cases
- Rapid healing when used with regular ulcer regimen
- Mildly astringent; may reduce digestive action, thus favor clot formation
- Demulcent; gelatinous consistency affords protective coating to ulcer

Modern non-alkaline therapy for peptic ulcer and gastric hyperacidity

Willful Carelessness

The willfully careless tuberculosis patient poses a problem in tuberculosis control of no mean proportions. Section 326-a of the Public Health Law is intended to meet this problem by providing proper means of restraint, but there are many factors that make it difficult for local health administrators to enforce provisions of the Public Health Law. With respect to those portions of the law and particularly of this section as it relates to tuberculosis, there are, according to Dr. Robert E. Plunkett, General Superintendent, Tuberculosis Hospitals of the Department of Health, State of New York, sufficient details in the law itself to guide health officers in its administration.

"First," says Dr. Plunkett, "if a complaint is made by a physician as to the possibility of a case of tuberculosis, because of careless habits, et cetera, being a menace to his contacts, the health officer is legally obligated to make such investigations as may be indicated to determine the validity of such complaint. He has many sources of information to assist him in this determination. Among these are the practicing physicians, public health nurses, perhaps the sanatorium superintendent, the clinic administrator, industrial associates, et cetera. While a health officer may for personal or professional reasons hesitate to prescribe the enforcement of this or other health laws, we should not lose sight of the fact that the law is very specific that he, as a public official, like all other public officials, is required to do his job without fear or favor."

The physicians of the state and the Medical Society of the State of New York are increasingly aware of the physicians' responsibilities in relation to tuberculosis and its control and are actively assuming leadership with respect to education of the profession

"Payments from the Trust Fund to general practitioners. . . . shall be made on the basis of fees for services rendered to individuals entitled to benefits, according to a fee schedule approved by the Surgeon General. . . . .

"The Surgeon General may prescribe maximum limits to the number of potential beneficiaries for whom a practitioner may undertake to furnish general medical benefit. . . . .

"The Surgeon General is hereby authorized to establish necessary and sufficient hearing and appeal bodies. . . . .

"The Surgeon General shall publish a list of institutions found by him to be participating hospitals. . . . . Inclusion of any institution upon such list shall, unless and until withdrawn by him, be conclusive. . . . .

"The Surgeon General and the Social Security Board may. . . . determine for any calendar year . . . .that every individual entitled to general medical benefit may be required by the physician furnishing such benefit to pay a fee with respect to the first service or with respect to each service in a spell of sickness or course of treatment.

"The Surgeon General and the Social Security Board jointly shall have the duty of studying and making recommendations as to the most effective methods of providing dental, nursing, and other needed benefits. . . . .

"The Surgeon General, after consultation with the Social Security Board, and with the approval of the Federal Security Administrator, shall make and publish such rules and regulations. . . . necessary to the efficient administration. . . . .

"The term 'laboratory benefit' means such necessary laboratory or related services, supplies or commodities. . . .as the Surgeon General may determine, including chemical, bacteriological, pathological, diagnostic and therapeutic x-ray, and related laboratory services, physiotherapy, special appliances prescribed by a physician, and eye glasses prescribed by a physician or other legally qualified practitioner.

"With respect to inclusion in the list of participating hospitals the Surgeon General may accredit a hospital for limited varieties of cases and may accredit an institution for the care of the chronic sick. . . . ."[1]

The fact that, if enacted, the bill would create a structure of political medicine at a cost of $3,048,000,000 yearly would mean, at least for the present, "deductions from many workers' wages of 20 per cent for income tax, 10 to 25 per cent for War Bonds, 12 per cent for social security, and such other special deductions as are already made in individual plants."[1] Since the bill evidently has the support of the American Federation of Labor, according to the statement of its president, at least a small portion of American labor may be assumed to be willing to pay the cost of the political enslavement of American medicine. We await, however, the opinion of the so-far silent majority of workers.

Government in this country must still be by consent of the governed. When that principle is abandoned or abridged, there is little left to fight for, or to live for. What the people want they can get by the orderly process of the exercise of free speech, the enjoyment of a free press, and the proper use of the ballot. We do not for a moment believe that the people of the United States want political medicine under the Surgeon General of the Public Health Service or any of the alphabetical agencies. Congress is now in recess. Legislators are at home. *S. 1161* cannot be considered until the Congress reconvenes in September. Now is the time for all who want a free practice of civil medicine in this country to fight for it. The exigencies of war have all but turned the system of medical education over to the War and Navy Departments for the duration, of necessity. Is it necessary or desirable to place the practice of civilian medicine under the Surgeon General of the Public Health Service, lock, stock, and barrel? To do so would be to betray a trust reposed in us by those of the profession in the services who are prepared to give the last full measure of devotion. We shall not betray that trust.

Let every physician in the State of New York communicate at once with his Senators,

PHYSICAL THERAPY IN PERIPHERAL NERVE INJURIES

RICHARD KOVÁCS, M.D., New York City

INJURIES to peripheral nerves in civil life are so infrequent, according to Pollock,[1] that no one individual has been able to gather enough personal material to make a profitable clinical investigation. Most of our present-day clinical routine in treating these cases dates back to World War I, and it must also serve as a basis for taking care of the casualties of the present war. Tables 1 and 2 show the percentage of peripheral nerve injuries and the order of their frequency in World War I:

TABLE 1.—PERIPHERAL NERVE INJURIES IN WORLD WAR I

	Percentage of Total Casualties	Percentage of Traumatism to Extremities
American Base Hospitals	4.5	14–16
French		18
German	1.5–2	

TABLE 2.—ORDER OF FREQUENCY OF PERIPHERAL NERVE INJURIES IN WORLD WAR I*

	U. S. Army	German Army
Total number	2,347	3,963
Ulnar	569	742
Musculospiral	529	936
Median	433	800
Sciatic	349	523
External popliteal	283	
Peroneal		183
Tibial		112
Brachial plexus	147	
Axillary		82
Musculocutaneous		71

These figures demonstrate that nerve injuries occur far more commonly in the upper extremity and that those of the musculospiral, ulnar, and median nerves are of major significance. Pollock states that of combination injuries those of median and ulnar nerves are the most common, while the radial and ulnar nerves are seldom injured in a combined lesion.

The author's experience in treating nerve injuries is chiefly derived from his early work at the Reconstruction Hospital following World War I. In three successive years the number of peripheral nerve injuries seen there was as follows: 119 in 1921, 90 in 1922, and 60 in 1923. In contrast, the average yearly number of cases seen in the recent fifteen-year period at the New York Polyclinic Hospital was from 30 to 40.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943

* American figures relate to cases present in U. S. General Hospital No. 10, on May 1, 1919.[2] German figures were taken from Foerster's report.[3]

Changes Following Nerve Injury

Traumatization of one or more nerves may be caused by a projectile, cut, blow, wrench, gradual compression, friction, or stretching; it may consist of a bruise, laceration, or complete severance, it may occur at the time of the original injury or several hours, weeks, or months after this injury. The microscopic changes and the coincident or subsequent syndromes will vary according to the extent of the trauma and its circumstances.

There are immediate or gradual loss of function in the affected parts, sensory changes, and typical posture. Histologically, in the distal part of the injured nerve, total or partial degeneration of the axis cylinder and muscle sheath occurs, while the affected muscle first shows fibrillation. Later its fibers become pale, shrink in size, and, if unsupported, stretch indefinitely. Coincidentally, typical changes in the electric excitability of the nerves and muscles occur, and there are also characteristic chemical changes in the muscles. Subsequently, the other soft parts, joints, bones, and tendons suffer from lack of nutrition and may develop adhesions, faulty positions, trophic ulcers, and other pathologic conditions. In certain partial and irritative lesions, dense fibrosis and muscle spasm develop. In neglected cases the muscles ultimately degenerate into fibrous tissue and fat.

Nerve Regeneration and Operative Treatment

In every nerve injury there is a spontaneous tendency for recovery by down-growth of axons from the central end of the nerve as long as the two ends remain in close approximation. The rate of growth of the axis cylinder is estimated to be 1 to 2 mm. per day. It varies in different nerves and, according to Tinel,[4] it is greatest in the radial, musculocutaneous, and external popliteal, while in the median and ulnar it is often slow and incomplete. Pollock states that if there is no evidence of regeneration from four to five months after complete paralysis of the radial and peroneal nerves, surgical exploration should be performed, while in case of complete paralysis of the ulnar nerve the fifth month may be considered the maximum time to wait for recovery.

There is no electrical or other test available which will ascertain whether or not there is a separation of nerve fibers to such an extent that spontaneous regrowth is possible. In case of

and of the public. For this reason a better understanding of the operation of the Public Health Law is imperative.

Lower court judges may commit a recalcitrant or willfully careless patient to a tuberculosis hospital in cases where the evidence indicates that the patient may be a menace. The law is very specific in making provision for such cases. "Moreover," says Dr. Plunkett, "this law is perfectly clear in its requirement that the patient adjust himself to the institutional environment and obey the rules. If the patient does not obey the rules, the law contains a provision whereby the superintendent may place the patient apart from other patients, and I would assume that a single room would be suitable for this purpose, and the superintendent may also 'restrain' such patient. This should not be interpreted as being physical restraint, or the installation of iron bars surrounding the patient. In actual practice, by taking the patient's clothes away from him reasonable restraint is secured. If the patient continues to be troublesome, the superintendent may and should order the patient returned before a magistrate and such magistrate under this same provision of the law has the authority to commit such a patient to an institution, or jail, ordinarily used for the commitment of persons guilty of disorderly conduct. The question has been raised by several men of the inadequate isolation facilities in jails. As a matter of fact, I wonder whether any better isolation facilities prevail than in jails or prisons. In most instances, the commitment of recalcitrant patients to a jail for a few days might be the very prescription which would have a salutary effect psychologically upon the patient, and perhaps a day or two of isolation and bread and water might make him amenable to reasonable compliance with medical direction and supervision. The claim has been made that many jailers, or sheriffs, do not like to take such patients. As a matter of fact, I do not know of any provision in any law which gives a sheriff the privilege of selecting what kind of 'guest' he may have in his jail or prison."

In a five-year period, ending December, 1942, "there was a total of 17,500 patients admitted to state, county, and city tuberculosis hospitals in upstate New York. Legal proceedings were initiated in 106 cases, of which 58 were committed to sanatoria and 5 to jail. This is but a fraction—and a very small fraction at that—of the entire number of patients introduced to the hospital phase of tuberculosis control. . . . .

"This problem may be defined in another manner which also presents a challenging picture. In the past five years during which 106 cases had legal procedures initiated, about 25,000 new cases of tuberculosis were reported. Of these, approximately 20 per cent were in the minimal stage of their disease. Assuming that most of the balance, or 80 per cent of these 25,000, had for varying periods of time a positive sputum, there is no denying that from the standpoint of achieving the optimum in early diagnosis we have a long way to go.

"It is my impression, therefore, that the Public Health Law is adequate from the standpoint of prosecuting the recalcitrant and careless tuberculous patient; that the use of this law as a threat, if and when we have exhausted all of our resources of education, guidance, and assistance, is extremely valuable. However, even a superficial study of the tuberculosis problem makes it apparent that our greatest need is an extension of public health knowledge, in the field of lay education, as well as medical education."

In carrying on this educational program, and particularly as it applies to health education in tuberculosis, it is evident that new methods of personalizing the individual patient or family problems that arise in relation to this disease must be found. It is evident also that more time on the part of specialized physicians must be devoted to the appraisal of broad social problems which often are more important and more decisive as far as the behavior of the patient or the family is concerned than the classical definition of rales or x-ray shadows. If the Public Health Law is adequate to control the willfully careless patient, there yet remains much to be done along the lines of cooperative educational endeavor to reach those in the minimal stages of the disease. Successful public health education should surely minimize the number of cases in which the Public Health Law must serve as a last resort.

PHYSICAL THERAPY IN PERIPHERAL NERVE INJURIES

RICHARD KOVÁCS, M.D., New York City

INJURIES to peripheral nerves in civil life are so infrequent, according to Pollock,[1] that no one individual has been able to gather enough personal material to make a profitable clinical investigation. Most of our present-day clinical routine in treating these cases dates back to World War I, and it must also serve as a basis for taking care of the casualties of the present war. Tables 1 and 2 show the percentage of peripheral nerve injuries and the order of their frequency in World War I:

TABLE 1.—PERIPHERAL NERVE INJURIES IN WORLD WAR I

	Percentage of Total Casualties	Percentage of Traumatisms to Extremities
American Base Hospitals	4.5	14–16
French		18
German	1.5–2	

TABLE 2.—ORDER OF FREQUENCY OF PERIPHERAL NERVE INJURIES IN WORLD WAR I*

	U. S. Army	German Army
Total number	2,347	3,963
Ulnar	560	742
Musculospiral	529	936

These figures demonstrate that nerve injuries occur far more commonly in the upper extremity and that those of the musculospiral, ulnar, and median nerves are of major significance. Pollock states that of combination injuries those of median and ulnar nerves are the most common, while the radial and ulnar nerves are seldom injured in a combined lesion.

The author's experience in treating nerve injuries is chiefly derived from his early work at the Reconstruction Hospital following World War I. In three successive years the number of peripheral nerve injuries seen there was as follows: 119 in 1921, 90 in 1922, and 60 in 1923. In contrast, the average yearly number of cases seen in the recent fifteen-year period at the New York Polyclinic Hospital was from 30 to 40.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

* American figures relate to cases present in U. S. General Hospital No. 10, on May 1, 1919.[2] German figures were taken from Foerster's report.[3]

Changes Following Nerve Injury

Traumatization of one or more nerves may be caused by a projectile, cut, blow, wrench, gradual compression, friction, or stretching; it may consist of a bruise, laceration, or complete severance, it may occur at the time of the original injury or several hours, weeks, or months after this injury. The microscopic changes and the coincident or subsequent syndromes will vary according to the extent of the trauma and its circumstances.

There are immediate or gradual loss of function in the affected parts, sensory changes, and typical posture. Histologically, in the distal part of the injured nerve, total or partial degeneration of the axis cylinder and muscle sheath occurs, while the affected muscle first shows fibrillation. Later its fibers become pale, shrink in size, and, if unsupported, stretch indefinitely. Coincidentally, typical changes in the electric excitability of the nerves and muscles occur, and there are also characteristic chemical changes in the muscles. Subsequently, the other soft parts, joints, bones, and tendons suffer from lack of nutrition and may develop adhesions, faulty positions, trophic ulcers, and other pathologic conditions. In certain partial and irritative lesions, dense fibrosis and muscle spasm develop. In neglected cases the muscles ultimately degenerate into fibrous tissue and fat.

Nerve Regeneration and Operative Treatment

In every nerve injury there is a spontaneous tendency for recovery by down-growth of axons from the central end of the nerve as long as the two ends remain in close approximation. The rate of growth of the axis cylinder is estimated to be 1 to 2 mm. per day. It varies in different nerves and, according to Tinel,[4] it is greatest in the radial, musculocutaneous, and external popliteal, while in the median and ulnar it is often slow and incomplete. Pollock states that if there is no evidence of regeneration from four to five months after complete paralysis of the radial and peroneal nerves, surgical exploration should be performed, while in case of complete paralysis of the ulnar nerve the fifth month may be considered the maximum time to wait for recovery.

There is no electrical or other test available which will ascertain whether or not there is a separation of nerve fibers to such an extent that spontaneous regrowth is possible. In case of

penetrating injuries the surgeon must decide on purely anatomic considerations whether to make an immediate nerve suture or not. Even immediate nerve suture, however, does not prevent subsequent nerve degeneration. In the majority of suspected incomplete nerve lacerations the tendency now is to wait and to make an exploratory operation only if (1) there is total loss of function for two months or more in an area exclusively supplied by a nerve, or (2) if recovery is extremely slow or there is a relapse, or (3) if there is a palpable neuroma at the site of the injury of a nerve, the function of which is seriously disturbed, or (4) if there is severe, persistent, and intractable pain.

Neurosurgeons emphasize the fact that while operative procedures in nerve injury make it possible for nerves to regenerate, they will not serve to restore function. It is conceivable that perfect regeneration might occur in the nerve and yet an extremity be functionless because of interphalangeal fibrosis, retraction of capsular ligaments, marked atrophy and fibrosis, shortening of muscles, spasms of muscles, and akylosed joints. This explains the importance of the early institution and systematic application in all nerve injuries of such measures which will tend to maintain nutrition and function in the affected parts.

Role of Physical Therapy

All surgeons who have treated large numbers of nerve injuries emphasize the fact that physical treatment is of immense value in both nonoperative and postoperative treatment.[1,5,6] Electrical testing is indispensable as an adjunct to diagnosis and follow-up of nerve injuries, with the large variety of physical treatment measures serving to stimulate circulation, maintain nutrition, conserve the function of muscles, prevent their overstretching, prevent adhesions and deformity from shortening of muscles, ankylosis of joints, and in the later stages to re-educate muscle function. The anatomic regeneration of the nerve itself can be assisted only indirectly by improvement of the circulation and nutrition.

The official *U.S. Army Report on Physical Reconstruction*,[2] issued at the end of World War I, outlines the duties of the physical therapy department in cases of nerve injuries as follows: "In the physiotherapy treatment of nerve injury cases it is essential that the director of physiotherapy make a clinical examination, together with a brief history. The following notations should be included on a suitable clinical record form: cause and date of injury; date of healing of wound; time of appearance of paralysis in relation to injury; treatment up to present time, including surgical measures; muscle groups paralyzed; area of sensory impairment; degree of atrophy; extent of fibrosis; presence of trophic ulcers; vasomotor changes and neuromata; formation on the 'D.T.P.' (distal tingling on percussion); measurement of girth of affected limb as compared with the opposite or normal limb, and measurements with suitable protractors of any limitation of joint mobility, if such is present. The electrical reactions should be taken, following which the specific treatment should be outlined, with proper instructions to the aide to whom the case is referred. A report is then sent to the surgeon of the findings of the electrical reactions, stating in terms of pathology the condition of the nerve as interpreted from the reactions, and the outline of treatment which the patient will receive. A monthly progress note and report to the surgeon is in order, with special reference to any material changes in electrical reactions, return of sensory or motor functions, progressive advancement of the D.T.P., and the like. The practice of personal consultations with the surgeon who has charge of the patient can well be emphasized."

Electrodiagnosis

The basic change in electrical reactions in the case of full paralysis is the typical R.D., or reaction of degeneration. The injured nerve does not respond to any form of electrical stimulation, while the affected muscles, because of the gradual process of degenerative change in their substance, cease to respond after the eighth day to a short electric stimulus (as furnished by the faradic current) but continue to respond, although sluggishly, to the longer stimulus of the make and break of a galvanic current. The occurrence of the reaction of degeneration signifies a separation—anatomic or physiologic—between a muscle and its trophic center and, therefore, may mean any of the following: complete section of the nerve, compression due to callus, degeneration of nerve after interstitial sclerosis (neuroma, hypertrophic interstitial neuritis), abolition of function of the trophic center in the spinal cord due to a lesion in the anterior horns (poliomyelitis, syringomyelia, etc.) or, finally, alteration of the peripheral nerve endings owing to toxic lesions. The presence of R.D. serves as an important guide in diagnosis and prognosis in diseases or injuries of the peripheral nerves, but it cannot determine whether the nerve has been divided or not, as already stated. On the other hand, since functional, hysterical paralyses and paralyses of cerebral origin are never accompanied by important disturbances of the electrical reactions, the absence of R.D. serves as important evidence in determining malingering or functional paralysis and in differentiating them from other

conditions. "Absolute" reaction of degeneration, consisting of total lack of response of the nerve or muscle to any electric stimulation, implies that the continuity of the nerve has been completely destroyed and that muscle tissue has been replaced by fibrous and fatty tissue. Prognosis for recovery is hopeless in these cases.

The classical faradic-galvanic test serves, however, only as a qualitative test. For measurement of the strength of current needed for stimulation, and for more exact prognosis and follow-up charting, the newer methods of condenser testing and chronaxie measurement furnish very desirable means. Testing by *condenser discharges* is based on the fact that the discharge of a condenser through a constant resistance varies in duration according to the capacity of the condenser. With a set of condensers of various capacities it is possible to obtain currents whose total duration varies from $^1/_{2100}$ to $^1/_{20}$ second. Instead of a long description of the type of response, a simple numerical equation (from 0.01 to 10 microfarads) is available and serves as a basis of comparative charting. In *chronaxie* testing, a current intensity of a known contractile effect upon an individual muscle or nerve is applied. The difference in time necessary to get a contraction is the only variable factor, and this can be accurately observed and recorded. The unit of measurement is the sigma, representing $^1/_{1000}$ of a second, and the results are recorded in decimal figures as in condenser testing. The application of these refined tests requires, on the other hand, special equipment, well-grounded technic and a great deal of time; hence for quick determination of the state of nerves and muscles, the classical faradic-galvanic method serves still as the simplest aid to the initial clinical examination.

Physical Treatment Measures

For physical treatment of nerve injuries a fairly large variety of treatment measures is available. However, their skillful employment requires painstaking institutional care or a well-equipped specialist's office. Nerve injuries as a rule cannot be treated either safely or efficiently in the office of the average general practitioner. Table 3 shows the variety of physical treatment measures and their object.

TABLE 3.—PHYSICAL TREATMENT MEASURES IN NERVE INJURIES

Form	Object	Period of Use
Splinting	Prevention of deformity	From beginning
Heating	Improvement of circulation and nutrition	From beginning
Electric muscle stimulation	Preserve functional capacity of muscles	From beginning
Passive movement	Prevent fibrosis and contractures	From beginning
Massage	Aid circulation, improve nutrition	From beginning
Active exercise	Re-education of muscle function	In later period
Occupational therapy	Hasten muscular recovery	In later period

Splinting.—Splinting is a measure of primary importance for maintaining the condition of paralyzed muscles and assuring a position of anatomic rest and complete relaxation of all paralyzed muscles. It will also prevent shortening of their antagonists. Splinting must be maintained until signs of voluntary motion appear, but it should not be kept up indefinitely, as prolonged immobilization in itself will cause periarticular joint changes and muscle atrophy. Many patients have been incapacitated by the fibrosis which has resulted from the prolonged and uninterrupted use of splints. Splints must be simple, light, easily applied, and easily removed.

Thermal Measures.—The object of thermal measures is to improve nutrition and relax muscles and prepare the limb for further treatment. The most convenient and safest measure for this purpose is the hot whirlpool bath, at a temperature of 100 to 105 F., in which the affected extremity should be submerged for at least half an hour. It combines sustained heat with gentle friction and under this combined action the previously cold, clammy, and often tender limb becomes warm, red, and painless. When the whirlpool bath is not available, a heat lamp or a nonluminous infrared generator may be applied for half an hour, at a distance of comfortable toleration. Because of the frequent prevalence of disturbed sensation, impaired circulation, and other trophic changes, all heat measures must be applied very cautiously in order to avoid the production of slowly healing burns. For the same reason the use of diathermy in these cases should be reserved for expert hands. It has been argued that diathermy exerts a more efficient heating effect in extensive muscle atrophy and that in early cases it may retard or arrest muscle fibrillation which, according to Langley,[7] always follows severance of the nerve and is the cause of muscle atrophy. Short wave diathermy is best applied with the inductance cable wound around the extremity and kept up for thirty minutes at a rate of moderate heating. Any method of heat treatment should be applied systematically, preferably daily, to accomplish the best results.

Electric Stimulation.—Electric muscle stimulation of the paralyzed muscles is an important standard measure of early physical treatment. Its rationale and the form of current most suitable have been subject to much controversy. When muscles are fully paralyzed and are unable to do

any active work, it would seem evident that a method which enables muscles to maintain part of their contractility and their nutrition is a desirable one. Electrical stimulation is the only known means for this purpose and its value is being attested by both clinical and experimental evidence. A recent editorial in the *Journal of the American Medical Association*[8] recalls that the earliest experimental work to prove the importance of electric stimulation in maintaining the nutrition of a muscle deprived of its nervous influence was performed over a hundred years ago, in 1841, by John Reid,[9] a young lecturer on physiology at the University of Edinburgh. The original object of his investigation was to settle the controversy over whether the property of muscle contractility is inherent in the muscle itself or is derived from the nervous system. In these experiments, the spinal nerves were cut across on four frogs, and the muscles of one of the paralyzed limbs were daily exercised by a weak galvanic battery, while the muscles of the other limb were allowed to remain quiescent. This was continued for two months, and at the end of that time the muscles of the exercised limb retained their original size and firmness and contracted vigorously, but those of the quiescent limb had shrunk to at least one-half of their former bulk and presented a marked contrast with those of the exercised limb.

Clinical experience in the treatment of the large number of cases of the war injured has amply established the value of electric muscle stimulation in peripheral paralysis. Pollock[1] states: "Electrotherapy serves to conserve vitality, prevent complete atonia, and increase the contractility of paralyzed muscles." Souttar and Twining[5] state: "Were we limited in the treatment of peripheral nerve injuries to one method of treatment and had nothing but the muscle to consider we should ourselves prefer electrical stimulation to all other methods." On the other hand, some orthopaedic specialists doubt any value of electrical muscle stimulation in paralysis and strongly voice their conviction that voluntary muscle exercise is the most desirable form of activity and no other form of exercise can have the same physiologic value. Experimental evidence is being cited that electrical stimulation cannot retard atrophy and degeneration of denervated muscle and that the degree of regeneration of the peripheral nerve is not influenced by physical measures (Chor *et al.*[10]). Tower[11] maintains that because the atrophy of denervated muscles is due to a continuous fibrillation, leading to exhaustion of the muscle, electric stimulation does not appear rational.

In confutation of such doubts, very recent experimental work has again corroborated the classical observations of Reid. Fischer[12] has shown that the suitable type of stimulation is effective in increasing the size of muscle fibers and their metabolic capacity; Gutmann and Guttmann[13] have demonstrated that electric stimulation accelerates the return of the muscle to its initial volume after reinnervation and possibly prevents atrophy, while Liebesny[14] proved that such stimulation can produce response even in a completely fatigued muscle. Finally, Hines[15] concluded that electrical stimulation to the point of overstretching and even local fatigue does not appear to be detrimental to any phase of neuromuscular regeneration. Thus, on the basis of extended clinical employment as well as on seasoned experimental evidence, the case still stands for the judicious employment of electric stimulation in peripheral paralysis as part of a well-rounded routine of physical treatment. In addition to the actual physiologic effect, the influence of systematic electric treatments on the morale of the patient must also be considered.

There is some controversy also concerning the most desirable form of electric stimulation and its extent. Since fully paralyzed muscles do not respond to the short impulse of a faradic current, this current is of no value in these cases. Active stimulation can be produced by the slow (galvanic) sinusoidal current. This consists of a slow surge of a galvanic current in one direction, followed by a similar one of the opposite polarity. Because of its effectiveness and relative painlessness, many clinicians, including the author,[16] prefer the slow sinusoidal current. Others, including Pollock, consider the make and break of the ordinary galvanic current (interrupted galvanism), although it is more painful and abrupt, just as effective. In recent years stimulation by a series of condenser discharges has been extolled abroad because of the possibility of affecting selectively the paralyzed muscles and leaving the normal ones unaffected (Turrell[17]). These observations have been corroborated here by Liebesny.[14]

In proceeding with the technic of electric stimulation, the first step is to warm the area of the paralyzed muscles to be treated. The muscles must be placed in a relaxed and supported position where they do not have to contract against gravity. The usual technic employs individual muscle stimulation, using a small disk electrode over or near the motor point—which is usually displaced distally—and a large dispersive electrode in a suitable location. In very weak muscles the bipolar method may be employed first, with two disk electrodes over either end of the muscle belly. This prevents spreading of the strong current to neighboring normal muscles and the misleading effect of such response. No vigorous contractions are to be elicited at any

time, for paralyzed muscles may get quickly exhausted. Harpuder[18] points out that as abnormal fatigability of the motor synapse and lack of energy material in the muscle are physiologically characteristic of denervation, strong stimulation of long duration requires caution. One should begin in early cases with two or three contractions daily to each muscle and gradually increase this number to thirty or forty per session. After many weeks or months of systematic daily stimulation there comes the first indication of the return of voluntary motion in one or more of the paralyzed muscles. This is proof that the nerve trunk and the motor endplate have regenerated. Response to the faradic current returns about this time or, as a rule, somewhat later. One must be careful not to replace the slow sinusoidal too quickly by the surging faradic current, for recovering muscles are sensitive toward more exhausting exercise and may be easily tired out.

Massage.—Massage as an aid to circulation and for the improvement of nutrition is a useful part of the routine physical treatment. So far as the prevention of muscle atrophy is concerned, massage is only of slight benefit. As a matter of fact, according to Mennell,[19] heavy massage is transmitted to the blood vessels and may cause paralytic dilatation. Massage should be always preceded by a thermal measure and administered to the well-supported and completely relaxed extremity. It should begin with rhythmic superficial stroking and continue with gentle kneading of the skin and of any contracted muscles, with friction over ankylosed joints. The average massage treatment should take from ten to twenty minutes.

Passive Movement.—Suitable manipulation of joints and stretching of muscles in peripheral nerve injuries is of even greater importance than routine massage; however, it is best carried on in conjunction with massage. Contractures and adhesion of joints, muscles, and tendons are due to shrinkage of newly formed connective tissue. Introductory heating and massage tend to soften this tissue and to promote its absorption, while gentle manipulation serves to stretch it and slowly free it. Such manipulation will also enable normal joints to keep active and increase the range of motion in those which already have become impaired. In manipulating a joint it is better to increase the movements which are not so much limited, and in the course of their restoration to normal, gradually to limber up the most obviously limited movements. The latter are resisted by the strongest adhesions. There is no reason for stretching under anesthesia in these cases because this is likely to cause considerable damage to the capsule and the periarticular tissues. Early and skillful employment of suitable passive movements and manipulation is the best preventative of the formidable ankylosis and contractures. In order to make possible this early treatment, splints must be removable, and in case of nerve suture passive movement should be instituted as soon as the condition of the scar permits—usually after two weeks.

Active Exercise.—Active exercise and re-education of muscle function comprise the most important part of the treatment after active power to the affected muscles has begun to return. This occurs, as a rule, not earlier than the fourth month after injury. However, a nerve injury causes loss of function of an extremity far beyond the structures that are actually involved, because the normal use of the extremity has been lost. Furthermore, the usual routine of splinting and immobilization tends to cause patients to restrict the use of the limb to a minimum. The early use of suitable exercises will reduce much of the unnecessary waste of muscles and stiffening of joints. Hence, even in the early treatment of nerve injuries, exercises are indicated for maintaining the function of muscles not directly affected and also for maintaining the full range of joint motion. When signs of active power appear in the affected muscles, the simplest possible active exercises with these muscles are begun, at first with as much assistance by the technician as required. Movements on a powdered board or under water will greatly aid in overcoming gravity and in allowing gradual redevelopment of function in the very weak muscles. Exercises must be carried on in all instances with the parts properly supported and previously warmed. It is very rarely necessary to use artificial exercise apparatus for this purpose, but use can be made of the various types of simple active exercise devices that are available. Overexercising must be avoided at all times.

Occupational Therapy.—The last stage of muscle re-education consists in active stimulation of the patient's efforts by occupational therapy. A well-equipped and supervised work shop, where various simple tools provide practical and attractive work, is most desirable for this purpose. The same setup can be used in cases where there is lack of recovery, to teach the injured to make the best use of what remains to him. Gymnastic exercises are also valuable in this stage for general muscle redevelopment and increase of coordination.

Summary

1. The importance of the proper diagnosis and care of peripheral nerve injuries is shown by the fact that their number in World War I amounted to 5 per cent of the total casualties and to almost one-fifth of all traumatism to the extremities.

2. Operative procedures in nerve injury make it possible for nerves to regenerate, but they will not serve to restore function. As long as there is end-to-end apposition of nerve endings, there is a spontaneous tendency for recovery in nerve injuries.

3. In all nerve injuries early institution and systematic, skillful application of physical measures are essential for maintaining nutrition and function in all affected parts. These measures comprise, in early stages, splinting, thermal measures, electric muscle stimulation, massage, and passive movement; in the later stages, active exercise and occupational therapy.

4. Electrodiagnosis furnishes an indispensable aid in the diagnosis and recording of progress in nerve injuries and in differentiation of malingering or functional paralysis.

Discussion

Dr. John H. Kohl, *Buffalo*—From an orthopaedic standpoint, peripheral nerve injuries present many complex problems, especially in so far as the treatment is concerned. It is true that our experience with this type of lesion is somewhat limited in civilian practice; nevertheless, these injuries must be dealt with so that the best results are obtained. It is within the province of the orthopaedic surgeon to prevent and correct deformities, and in these particular injuries prevention of deformity is the main goal.

In our experience, too, peripheral nerve injuries are most common in the upper extremities. Everyone is familiar with the damage to the musculospiral nerve that results from sleeping with one arm over the back of a chair and awakening in the morning with a wristdrop. Fractures in the region of the elbow, especially in children, account for many peripheral nerve injuries. It is always well to make sure before any manipulation of the elbow that there is no nerve injury and this should be tested very diligently so that after the reduction and application of a cast there is no question as to whether the nerve injury was present before any manipulation. This particular instance also has its medicolegal aspects.

Injury of the ulnar nerve produces the typical clawhand with atrophy of the hypothenar eminence, dorsal and ventral interossei, and lumbricalis muscles, with contraction of the fingers and fibrosis between the phalanges and ankylosed joints.

In the lower extremity, injuries to the external popliteal nerve are the most common in our experience. We have seen them as a result of an overly tight cast that presses on the external popliteal nerve as it winds around the upper end of the fibula, resulting in paralysis of the extensors of the foot and causing footdrop. This, we feel, is preventable if the cast is properly applied.

As far as treatment is concerned, proper splinting is of utmost importance, whether the nerve injury be caused by complete section, compression of the nerve from calluses, toxic lesions, or any cause whatsoever. In the wrist, for instance, in musculospiral paralysis, a cock-up splint should be applied, not to the extreme degree but enough to allow the paralyzed muscles to rest and to prevent the flexors from shortening. The splints should be so constructed as to allow for easy application and removal so that physiotherapy measures can be readily instituted. The splints should be light and not cumbersome.

I was pleased to hear Dr. Kovács mention his use of the hot whirlpool baths. We are very fond of this type of treatment because it improves the circulation in a cold and clammy extremity and helps to prevent fibrotic changes. In the use of diathermy, Dr. Kovács makes a good practical point in warning against the possibility of burns as a result of impaired sensation. We feel that massage when applied by an experienced masseur is a useful agent in promoting circulation. Passive motions are of the utmost value in preventing adhesions and contractures and therefore one of the most important physical therapy measures. We do not advocate stretching or breaking up adhesions under anesthesia because such manipulation causes more damage and in a short time the same conditions obtain and sometimes actually become worse.

Active exercises and occupational therapy certainly play a big part in the recovery of these patients.

In conclusion I would like to emphasize: (1) prevention of deformities in these cases, (2) the early use of suitable splints, and (3) the judicious use of physical therapy measures from the very beginning.

SULFONAMIDE THERAPY OF OCULAR INFECTIONS

P. THYGESON, M.D., and WILLIAM STONE, JR., M.D., New York City

THE sulfonamide drugs have come into wide use in the treatment of ocular infections and the literature now contains a considerable number of reviews and reports recording their favorable action. They have been used at the Institute of Ophthalmology since 1938 for the treatment of ocular infections, and the present report is a summary of the results obtained with the oral treatment of a total of 152 cases. In addition, sulfonamide ointments have been employed successfully in a large series of blepharitis, conjunctivitis, and keratitis cases at Vanderbilt Clinic, but these results will be the subject of a later report.

Methods of Treatment

Five sulfonamide preparations—sulfanilamide, azosulfamide (neoprontosil), sulfapyridine, sulfathiazole, and sulfadiazine—have been employed in this series. In most instances treatment was given under the direction of members of the staff of the Department of Medicine of the College of Physicians and Surgeons. In general, the drugs were administered in such a manner and dosage as to give blood concentrations varying from 5 to 10 mg. per cent, and the usual precautions as to fluid intake, blood counts, urine examinations, etc., were taken. In certain cases sulfonamide preparations were employed locally (in solution, ointment, or powder form) to supplement the oral therapy.

Results of Sulfonamide Therapy

Trachoma.—In 1940 the results obtained with sulfanilamide in the treatment of 31 cases of trachoma were recorded.[1] Of this number 16 were healed, 11 showed satisfactory improvement, and 4 showed little or no change. The 16 healed cases have now been followed for at least two years and there have been no recurrences. Of the 11 cases classified as improved, 7 have since become clinically well; 2 recurred but have responded well to a second course of sulfonamide therapy; and the remaining 2 have continued to show symptoms of minor irritation, but these appear to be due in one case to persistent Klebsiella pneumoniae (Friedländer) infection and in the other to deficient tear formation, probably the result of scar tissue development in the upper fornices. The 4 cases described as showing little or no improvement have remained unchanged up to the present time, but the prominence of such secondary factors as bacterial infection, trichiasis, and tear deficiency in all 4 suggest that the inflammatory signs may be due to one or more of these factors rather than to any residual trachoma. This interpretation is borne out by the fact that repeated attempts to demonstrate inclusion bodies in these cases have failed. So far as is known, therefore, none of the 31 cases is now showing evidence of active trachoma.

Since this earlier report was published, 23 additional cases of trachoma have been treated, 21 with sulfanilamide, and 2 with sulfathiazole. Complete healing was obtained in 15, satisfactory improvement in 3, and little or no improvement in 3. Of the 15 cases classified as healed there have been no recurrences to date. Of the 3 showing improvement, one left the hospital before the treatment was completed and has not been seen since, one had severe toxic signs necessitating interruption of therapy, and the third showed marked improvement but still retained some residual punctate staining of the cornea and irritation of the conjunctiva, probably the result of deficient lacrimal secretion. Of the 3 cases classified as unimproved, one was a cicatricial trachoma of advanced degree, one was a cicatricial trachoma with xerosis, trichiasis, and lacrimal deficiency, and one was a case in which the diagnosis was in doubt. All three were inclusion-negative. In these cases, therefore, there was no proof of trachomatous activity, and it seems likely that in at least 2 of the 3, the trachoma had been inactive prior to the institution of the sulfonamide therapy. It must be concluded that sulfanilamide, and in 2 cases sulfathiazole, were remarkably effective in the treatment of the trachoma cases in this series and that complete and apparently permanent cures were obtained in cases uncomplicated by such factors as deficient lacrimal secretion, secondary infection, and trichiasis.

As in the series previously reported, there was considerable difference in the rapidity of the response of trachoma cases according to the stage and severity of the disease. Corneal lesions responded much more rapidly than palpebral lesions, and papillary hypertrophy more rapidly than follicular hypertrophy. The disappearance of corneal lesions, including punctate fluorescein-staining spots and subepithelial infiltrates, furnished an important guide to therapy. It was found that therapy could be stopped safely as soon as the cornea became free from punctate

Results of Sulfonamide Therapy

Trachoma.—In 1940 the results obtained with sulfanilamide in the treatment of 31 cases of trachoma were recorded.[1] Of this number 16 were healed, 11 showed satisfactory improvement, and 4 showed little or no change. The 16 healed cases have now been followed for at least two years and there have been no recurrences. Of the 11 cases classified as improved, 7 have since become clinically well; 2 recurred but have responded well to a second course of sulfonamide therapy; and the remaining 2 have continued to show symptoms of minor irritation, but these appear to be due in one case to persistent Klebsiella pneumoniae (Friedländer) infection and in the other to deficient tear formation, probably the result of scar tissue development in the upper fornices. The 4 cases described as showing little or no improvement have remained unchanged up to the present time, but the prominence of such secondary factors as bacterial infection, trichiasis, and tear deficiency in all 4 suggest that the inflammatory signs may be due to one or more of these factors rather than to any residual trachoma. This interpretation is borne out by the fact that repeated attempts to demonstrate inclusion bodies in these cases have failed. So far as is known, therefore, none of the 31 cases is now showing evidence of active trachoma.

Since this earlier report was published, 23 additional cases of trachoma have been treated, 21 with sulfanilamide, and 2 with sulfathiazole. Complete healing was obtained in 15, satisfactory improvement in 3, and little or no improvement in 3. Of the 15 cases classified as healed there have been no recurrences to date. Of the 3 showing improvement, one left the hospital before the treatment was completed and has not been seen since, one had severe toxic signs necessitating interruption of therapy, and the third showed marked improvement but still retained some residual punctate staining of the cornea and irritation of the conjunctiva, probably the result of deficient lacrimal secretion. Of the 3 cases classified as unimproved, one was a cicatricial trachoma of advanced degree, one was a cicatricial trachoma with xerosis, trichiasis, and lacrimal deficiency, and one was a case in which the diagnosis was in doubt. All three were inclusion-negative. In these cases, therefore, there was no proof of trachomatous activity, and it seems likely that in at least 2 of the 3, the trachoma had been inactive prior to the institution of the sulfonamide therapy. It must be concluded that sulfanilamide, and in 2 cases sulfathiazole, were remarkably effective in the treatment of the trachoma cases in this series and that complete and apparently permanent cures were obtained in cases uncomplicated by such factors as deficient lacrimal secretion, secondary infection, and trichiasis.

As in the series previously reported, there was considerable difference in the rapidity of the response of trachoma cases according to the stage and severity of the disease. Corneal lesions responded much more rapidly than palpebral lesions, and papillary hypertrophy more rapidly than follicular hypertrophy. The disappearance of corneal lesions, including punctate fluorescein-staining spots and subepithelial infiltrates, furnished an important guide to therapy. It was found that therapy could be stopped safely as soon as the cornea became free from punctate

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1942.

From the Institute of Ophthalmology, Presbyterian Hospital, and the Department of Ophthalmology, College of Physicians and Surgeons, Columbia University.

epithelial lesions, irrespective of the state of the conjunctiva. There have as yet been no recurrences in cases in which the corneae became entirely clear. While papillary hypertrophy regressed rather rapidly, conjunctival follicles, including limbal follicles, often required as long as six weeks to be absorbed.

From the experience in this series it seems safe to conclude that excessive blood concentrations of the drug are not required for the treatment of trachoma, a concentration of from 3 to 5 mg. per cent for two weeks often being sufficient.

Inclusion Conjunctivitis.—The rapid curative effect of sulfanilamide in 15 cases of inclusion conjunctivitis occurring in this series has already been reported.[2] In these cases the drug given orally was even more strikingly effective than it was in cases of trachoma. More recently the curative effect of 5 per cent sulfathiazole ointment employed locally in 15 cases of inclusion conjunctivitis in the newborn has been recorded.[3] In the infants this local treatment appeared to be as effective as oral therapy, but this was not the case in children and adults, some of whom required supplemental oral therapy. This difference in response between the infant and the adult may possibly be related to tear production. In the newborn infant tears are minimal and therefore do not dilute the drug as they do in the adult.

It may be said that inclusion conjunctivitis is one of the most satisfactory eye infections to treat with the sulfonamide drugs.

Lymphogranuloma Venereum.—No cases of lymphogranuloma venereum are included in this series, but it is of interest to refer to the report of Curth, Curth, and Sanders,[4] in which a case of primary lymphogranuloma venereum of the eye, giving the picture of Parinaud's oculoglandular conjunctivitis, was treated successfully with sulfanilamide at Vanderbilt Clinic.

Gonococcal Conjunctivitis.—Two cases of gonorrheal ophthalmia were treated with sulfanilamide, and 2 were treated with sulfathiazole, all with rapid cures. In all 4 the rapid disappearance of inflammation and discharge was dramatic. No corneal complications occurred. Smears and cultures all became negative within five days, and in two instances within forty-eight hours. No supplementary local therapy other than irrigation with normal saline or boric acid solution was employed.

Streptococcic Membranous Conjunctivitis.—In this series there were 2 cases of severe membranous conjunctivitis due to beta hemolytic streptococci. One of these responded rapidly and completely to sulfathiazole orally combined with 5 per cent sulfathiazole ointment locally. The membrane which involved the bulbar conjunctiva disappeared on the second day of treatment and the eye returned to normal within a week.

The second case was that of a young Negro girl who came to Vanderbilt Clinic with a bilateral membranous conjunctivitis of five days' duration, dense membranes covering the entire conjunctival surfaces and corneae. Sulfadiazine orally in full dosage combined with sulfadiazine powder locally failed to influence the disease, which progressed to complete destruction of both globes. The organism was found to be a group A type 25 streptococcus susceptible in vitro to sulfanilamide and the other sulfonamides. A change to sulfanilamide orally combined with sulfanilamide powder locally was no more effective. Six weeks after onset, when the membranes had been mechanically removed, the organisms disappeared.

This failure of a sulfonamide-susceptible organism to respond to sulfanilamide or sulfadiazine is believed to be related to the amount of tissue destruction that was present. It is well known that the action of the sulfonamides is inhibited by broken-down cell products.

Catarrhal Conjunctivitis.—In this series only 3 cases of catarrhal conjunctivitis were hospitalized for oral therapy. A severe Haemophilus influenzae conjunctivitis of unusual severity became symptom-free in forty-eight hours on oral sulfanilamide combined with 0.8 per cent sulfanilamide solution used as an irrigation fluid. One case of severe chronic catarrhal conjunctivitis, in which an organism of the Proteus group was the only pathogen present, yielded rapidly to sulfathiazole but recurred a few weeks later. One severe staphylococcic blepharoconjunctivitis became symptom-free after a course of sulfathiazole, but the organisms persisted in the meibomian glands, and the conjunctivitis later recurred. The recurrence was controlled by staphylococcus toxoid combined with sulfathiazole ointment.

As has been reported in detail in a later communication,[5] a series of over 100 cases of catarrhal conjunctivitis due to Diplococcus pneumoniae, Staphylococcus aureus, and H. influenzae responded well to 5 per cent sulfathiazole ointment.

Conjunctivitis of Unknown Cause.—In this series, there were a number of cases of conjunctivitis of unknown cause. One case of acute ocular pemphigus, with skin and other mucous membrane involvement, failed to respond to sulfanilamide, and a case of severe chronic pemphigus showed no improvement on neoprontosil (azosulfamide). As was expected, 2 cases of vernal catarrh were uninfluenced by sulfanilamide. One of 3 cases of severe chronic conjunctivitis of nonspecific character failed to respond to sulfonamide therapy. A second case in which

bacteria of the Lactobacillus group were constantly present, cleared temporarily on sulfathiazole but promptly recurred. The development of a sensitivity to sulfathiazole prevented its re-use, and courses of sulfapyridine and sulfadiazine failed to affect the recurrence. A third case, a severe keratoconjunctivitis, is of special importance and warrants reporting in some detail:

P. M., a man, age 27, developed in 1936 a severe nonspecific keratoconjunctivitis whose cause could not be determined. Treatment failed to ameliorate the condition, and the keratitis progressed to complete corneal vascularization in each eye. The condition was not affected by local antiseptic therapy of many kinds and resisted a course of sulfanilamide. It responded brilliantly to sulfathiazole, however, but the sulfathiazole had to be terminated after ten days because of a febrile reaction. Following cessation of treatment, the ocular inflammation and discharge soon recurred. A course of sulfapyridine lasting five days was terminated because of severe nausea and vomiting. The drug had failed to affect the disease. The use of a 1 per cent sulfathiazole ointment locally effected an immediate cure which has now lasted nineteen months. Vision improved to 20/30 in the left eye and to 20/50 in the right eye and the patient has been able to obtain employment. The conjunctiva on healing showed very fine scarring suggestive of trachoma, but at no time were tarsal follicles, limbal follicles, inclusion bodies, or other pathognomonic signs of trachoma observed.

Blepharitis.—Two cases of blepharitis in which Staph. aureus was the infectious agent failed to respond to oral sulfanilamide but healed on treatment locally with sulfathiazole ointment. Three cases treated orally with sulfathiazole improved strikingly but were not permanently cured, and one treated with sulfadiazine failed to improve. All 4 cases eventually became symptom-free on sulfathiazole ointment combined with staphylococcus toxoid injections.

Impetigo.—There were no cases of impetigo treated orally in this series, but 4 cases of the disease, in which Staph. aureus appeared to be the sole pathogen, responded rapidly and completely to 5 per cent sulfathiazole ointment used six times daily.

Dacryocystitis.—Three cases of acute dacryocystitis (caused by pneumococci in 2 cases and by beta hemolytic streptococci in one) responded dramatically and rapidly to sulfathiazole and to sulfanilamide (streptococcus case) by mouth. The streptococcic case was important because of the severity of the associated conjunctivitis which was pseudomembranous in character.

Dendritic Keratitis.—Three patients with dendritic keratitis (herpes corneae) were treated with sulfonamide drugs; 2 with sulfanilamide-treated cases showed apparent response to therapy, but it was not possible to follow the patients for recurrences. The other case was unimproved by sulfadiazine and was later treated by curettage and iodinization.

In view of the known failure of the sulfonamides to affect typical viruses, it seem sunlikely that the two apparent successes were indicative of specific sulfonamide action.

Other Keratitis Cases of Virus Origin.—A single case of herpes zoster keratitis failed to respond to sulfanilamide therapy. A case of severe superficial keratitis with pannus secondary to a molluscum nodule of the upper lid likewise failed to respond to sulfanilamide therapy but healed rapidly when the nodule was removed. One case of epidemic keratoconjunctivitis failed to respond to sulfadiazine therapy used locally, and 3 similar cases were not affected by 5 per cent sulfathiazole ointment used locally.

Keratitis of Unknown Cause.—Three cases of severe keratitis of unknown cause differed in their response to sulfonamide therapy; one, a superficial keratitis with vascularization, responded rapidly and completely to sulfathiazole, while the other 2, treated by sulfathiazole and sulfanilamide respectively, failed to respond in any way.

Corneal Ulceration.—Two cases of Mooren's ulcer were treated with sulfanilamide without result. One of these was later arrested by delimiting keratotomy combined with repeated paracenteses.

Marginal ulceration from which Staph. aureus could be recovered responded satisfactorily to sulfathiazole, local application of the ointment form appearing to be quite as effective, or perhaps more effective, than oral administration. Marginal ulceration of unknown cause, particularly that type in which there were multiple foci—the so-called "ring ulcer" which occur most commonly in elderly women, failed completely to respond to the sulfonamides, either orally or locally in ointment or powder form. There were 6 examples. One case of marginal ring infiltration of unknown cause, believed endogenous in origin, responded rapidly and apparently completely to sulfathiazole.

There were 4 cases of serpent ulcers due to pneumococci. Three of these responded satisfactorily to sulfapyridine, although not so rapidly as had been expected in view of the favorable results of sulfapyridine chemotherapy in pneumonia. The fourth case was treated with sulfanilamide, but failed to respond. This was to be expected in view of the well-known resistance of pneumococci to sulfanilamide.

One case of hypopyon ulcer due to beta hemolytic streptococci responded dramatically to sulfanilamide, a change for the better being manifested as early as twenty-four hours after

TABLE 1.—Ocular Infections Which Should Respond Well to Sulfonamide Therapy

Virus infections	Gonococcus infections

Streptococcus viridans	Keratitis
Conjunctivitis	Moraxella lacunata (diplo bacillus of Morax-Axenfeld)
Endophthalmitis	Conjunctivitis*
Klebsiella pneumonia (Friedlander)	Marginal ulcers*
Ulcers	Moraxella duplex (diplo bacillus of Petit)
	Central ulcers

* Local therapy more important

the first administration of the drug. The eye healed with an inconspicuous nebulous opacity permitting useful vision. Since the ulcer involved the pupillary area, treatment that required cauterization would undoubtedly have resulted in complete loss of vision.

One ulcer in which both Friedlander and pyocyaneus bacilli were present responded dramatically to sulfadiazine orally supplemented by sulfadiazine powder locally, useful vision being retained. A second ulcer due to the pyocyaneus bacillus alone responded satisfactorily to sulfadiazine orally combined with sulfadiazine powder locally.

There were 7 acute ulcers in which the causation was not determined. It is noteworthy that all of these responded satisfactorily to sulfonamide therapy.

Uveitis.—A total of 11 patients with uveitis were given oral sulfonamide therapy, 3 with sulfathiazole, 3 with sulfanilamide, and 5 with sulfadiazine. Only 2 of the 11 showed improvement which could be considered significant. One of these had a history of previous gonorrheal urethritis and the fibrinous character of the anterior chamber exudate suggested a gonococcal cause. This relative failure of the sulfonamides to affect uveitis, which confirms the results reported by Guyton[6] and by Guyton and Woods,[7] must be considered as some indication that uveitis, in general, is not caused by direct metastasis to the uveal tract of sulfonamide-susceptible bacteria.

Endophthalmitis.—There were 15 cases of endophthalmitis and panophthalmitis in this series. Seven of them responded significantly to sulfonamide therapy, 4 of the 7 dramatically. In 6 of the 7 cases, Staph. aureus was the probable causal organism. The cases in which the probable causal agents were hemolytic streptococci, Pseudomonas pyocyanea, and D. pneumoniae failed to respond.

Toxic Effects of Sulfonamide Therapy.—There was only one serious toxic complication in this series of sulfonamide-treated patients. This was a hemolytic anemia in a colored man treated with sulfanilamide for a uveitis. A transfusion was required but recovery from the anemia was rapid. Other complications were of minor importance and consisted principally of fever and dermatitis with mild anemia developing in some of the trachoma cases which were treated for relatively long periods of time. A few individuals developed a sensitivity to sulfathiazole ointment used locally, reacting with a conjunctivitis and dermatitis of the eyelids. No local sensitivities have as yet been observed to sulfadiazine ointment.

Comment

The results in this series parallel closely those obtained in similar series reported by Guyton[6] and Guyton and Woods,[7] from the Wilmer Institute. The Wilmer series, however, includes data on several additional infections—namely, meningococcus panophthalmitis, orbital cellulitis of unknown cause, and corneal ulcer apparently due to Shiga dysentery bacillus. The first two infections responded dramatically to sulfonamide therapy, the third doubtfully.

Our findings appear to be in agreement with those reported by most other observers, but no attempt has been made in this report to review the literature. However, on the basis of data contained in this and other reports, ocular infections have been divided tentatively into 3 groups according to their probable response to

the sulfonamides. Table 1 lists the infections which should respond well, Table 2 the ocular diseases in which sulfonamide therapy is worthy of trial, and, Table 3, those diseases in which sulfonamide therapy is probably of little or no value. It will be noted that Tables 1 and 2 include several diseases, such as ocular actinomycosis and Clostridium welchii endophthalmitis, etc., for which no data on eye infections are available as yet. They were included because of reports of their sulfonamide-susceptibility when localized elsewhere in the body.

It is to be expected that there will be an increase in the local use of sulfonamide preparations. Local use has two distinct advantages: (1) that general toxic reactions can be avoided and (2) that much higher local concentrations can be obtained. The main disadvantage of local therapy is that continuous twenty-four-hour concentrations are difficult to maintain. For this reason solutions would appear to have little value for lid, conjunctival, and corneal conditions. The drugs in ointment or powder form, however, seem to be effective in many instances.

TABLE 3.—OCULAR INFECTIONS IN WHICH SULFONAMIDE THERAPY PROBABLY IS OF NO VALUE

Nonhemolytic streptococcus infections	Ocular pemphigus
Orbital cellulitis	Typical virus infections
Endophthalmitis	Herpes corneae (dendritic keratitis)
Corneal ulcers	Herpes zoster
Tuberculosis	Variola
Uveitis	Vaccinia
Conjunctivitis	Measles, etc.
Keratitis	Uveitis (idiopathic)
Tularemia	Sympathetic ophthalmia
Leptotrichosis conjunctivae (Parinaud's conjunctivitis)	

Conclusions

1. A series of 152 ocular infections treated by peroral administration of the sulfonamide drugs at the Institute of Ophthalmology are analyzed.

2. Infections responding rapidly to oral sulfonamide therapy included: (1) conjunctivitis due to Neisseria gonorrhoeae, H. influenzae, and beta hemolytic streptococci, as well as trachoma and inclusion conjunctivitis, (2) acute dacryocystitis due to D. pneumoniae, Streptococcus haemolyticus, and Staph. aureus, and (3) corneal ulcers due to Streptococcus haemolyticus and Ps. pyocyanea.

3. Infections responding definitely but slowly or incompletely included (1) blepharitis due to Staph. aureus, (2) conjunctivitis due to coliform bacteria and Staph. aureus, and conjunctivitis secondary to Streptothrix concretions of the canaliculi, (3) corneal ulcers due to Staph. aureus and D. pneumoniae, and (4) endophthalmitis due to Staph. aureus.

4. Ocular infections responding either very slightly or not at all to sulfonamide therapy included acute and chronic pemphigus, Parinaud's conjunctivitis (leptothricosis conjunctivae), Mooren's ulcer, herpes zoster ophthalmicus, dendritic keratitis, sympathetic ophthalmia, idiopathic uveitis, and endophthalmitis due to hemolytic streptococci, Ps. pyocyanea, and D. pneumoniae.

5. Sulfadiazine (because of its low toxicity and wide range of activity) appeared to be the drug of choice for oral administration in most ocular infections susceptible to sulfonamide therapy.

6. Local sulfonamide therapy has been employed with success in superficial infections, including blepharitis, conjunctivitis, and corneal ulceration. Sulfathiazole ointment in blepharitis and conjunctivitis, and sulfadiazine powder in corneal ulceration appear to be especially valuable. Combined oral and local therapy may be used with advantage in severe infections.

7. Sulfonamide therapy has revolutionized ocular therapeutics.

Discussion

Dr. L. Maxwell Lockie, *Buffalo*—This paper is a real contribution to medical literature. It is most thorough and carefully controlled. The range of eye conditions covered is broad. I have enjoyed the privilege of reading the paper and listening to the presentation at this time.

From the standpoint of the internist, there is no choice as to the type of sulfonamide therapy to be used. It is sulfadiazine or sodium sulfadiazine. These drugs have been shown to be just as effective as sulfanilamide, sulfapyridine, or sulfathiazole. In carefully controlled cases, the use of the other sulfonamides has not influenced the general course of the disease if sulfadiazine was ineffective.

Sulfadiazine was described in 1940 by Roblin and others. It can be given orally or locally. The sodium salt is the one used when other routes are necessary. If it is given orally, higher blood levels will occur (8 to 12 compared to 12 to 15 mg. per cent).

It is readily taken by most patients. After oral administration is begun, the drug slowly appears in the blood stream and the peak is attained in six to eight hours. If a more rapid absorption of the drug is necessary, then the intravenous route may be used at the beginning of treatment, which may be started by the oral route at the same time.

The drug is excreted slowly—approximately 50

per cent will be excreted in twenty-four hours and measurable amounts are present in the blood for several days. Excretion is through the kidneys.

With doses given every four to six hours, it is easy to maintain a blood level that is satisfactory. This is in the neighborhood of 15 mg. per cent. In seriously ill patients it may be held as high as 20 mg. per cent. A small proportion of the drug is in a conjugated form in the blood. It penetrates the red blood cells more readily than other forms of the sulfonamides.

Maintenance dose with constant urinary output will show an excretion of 50 to 75 per cent daily in the urine. Within thirty minutes after the drug is ingested orally, it begins to appear in the urine. If given intravenously there will be traces in the urine immediately.

The studies on the solubility of sulfadiazine are interesting. At 37 C. it registers 12 mg. per cent in water, 19 mg. per cent in normal saline, and 204 mg. per cent in whole blood.

When a large series of cases is reported, it is seen that sulfadiazine acts more favorably than the other sulfonamide drugs. That is, more patients with pneumonia are better at the end of thirty-six hours if they are kept on sulfadiazine.

After reviewing very briefly the pharmacology of sulfadiazine, one wonders if it can be given to everyone without harm. For practical purposes it can, but Dr. Thygeson and Dr. Stone have shown that there are a few toxic reactions. The more sulfonamide preparations developed, the less toxic they are.

It is possible and safe to give sulfadiazine to the ambulatory patient. With sulfanilamide, sulfapyridine, and sulfathiazole it was advisable to have the patient hospitalized because of the dizziness and mental uncertainty which went with effective dosage. These symptoms do not occur with sulfadiazine.

However, a few patients may be nauseated after taking the drug for several days. It should be stopped when this occurs. A few will have fever. This may come on insidiously or very suddenly, with or without headache and malaise. Occasionally a rash is noted. Most common of all is pain in the flanks and the presence of crystals in the urine. Hematuria may occur, but no kidney damage persists. Occasionally a mild conjunctivitis occurs, accompanied by congestion of scleral vessels.

Shifting from other sulfonamide drugs to sulfadiazine because of toxic manifestations resulted in prompt subsidence of these toxic signs even though there was no rest interval. Therefore, patients sensitive to other forms may tolerate sulfadiazine. Sulfadiazine failed in some cases, but the other sulfonamides failed in the same cases.

Sulfadiazine is the drug of choice when any of the sulfonamide group is indicated.

"DOCTOR JONES" SAYS—

These drug addicts—morphine and so on—I was talking to a fellow that's connected with the Health Department (their Narcotic Bureau) and, you know, that's quite a problem. There's thousands of 'em—these addicts and right now they're up against it. Of course the law—a doctor can prescribe a narcotic for a patient he's examined and found something the matter with him. But the majority of 'em—they aren't patients of any doctor and if they were they wouldn't be satisfied with the amount of the drug the doctor'd give 'em. You see the ordinary dose of morphine is around a quarter of a grain and some of these folks—they've been taking as high as ten or fifteen grains at a dose.

In the past they've been getting their supplies—most of 'em have—through "underground" channels: dope peddlers and so on. But now, on account of the war the opium supplies have been cut off (that's what morphine's made from) and in fact we haven't got enough to meet our legitimate needs. So the addicts have turned to all kinds of tricks: stealing from hospitals, forging doctors' prescriptions, visiting one doctor after another, and what not.

And a real drug addict—if he runs out of his drug he's practically crazy and there ain't much of anything he won't do to get it.

Of course we're apt to think of these people as underworld characters—call 'em dope fiends and all that. But we don't want to forget that it's awful easy to get a drug habit and a lot of fine people have been caught in the net. Sometimes they get loose from it but it's a tough fight and it takes a lot of character and backbone. I can think of two good friends of mine—one of 'em a very capable doctor—that used to be addicts years ago and were completely cured. There's no kind of treatment you can depend on—not unless they've got the courage and determination to fight it out. Most of 'em, when it once gets hold of 'em—you can lock 'em up and get 'em off from it for a while but when they get out they'll go back to it.

And it's a problem for the doctors—these addicts are. You hate to turn 'em out when you know they're suffering. But if you give 'em the drug, it won't be long before they'll be back and doctors have gotten into trouble being too kind-hearted. And there's practically no place where you can send 'em for treatment where they'll have to stay. The way it looks to me: there ought to be a state institution where they could be committed. Some of 'em could be cured and the rest of 'em—well, it'd get 'em off'm the doctors' necks, if nothing more.—*Paul B. Brooks, M.D., in Health News*

STRUTH!

"Sympathy in the practice of medicine," announced *Dr. DeWitt Neighbors*, of Fort Worth, "is like the air on the inside of a tire. There may be nothing to it, but it eases many a jolt and saves many sore spots."—*Texas State J. M.*

DIPLOMACY

"Why," demanded *Dr. Edward Randall, Jr.*, of Galveston, "do you look at your watch so often?"

"I was afraid," hastily responded the medical student, "that you would not have time to finish your interesting lecture."—*Texas State J. M.*

THE PROBLEM OF SELF-ESTEEM IN PSYCHOTHERAPY*

LEWIS R. WOLBERG, M.D., Kings Park, New York

ONE of the most difficult problems in psychotherapy is how to deal with the inordinately low self-esteem of the emotionally ill person. The problem is important because it is manifestly impossible for an individual to attain to mental health without a wholesome attitude toward himself as a human being.

The constellation of devaluated self-esteem is encountered with surprising frequency in our culture. Sometimes it is the presenting symptom of the neurosis, the patient manifesting ideas of worthlessness, inadequacy, and self-condemnation. More often it lurks subversively in the unconscious, giving rise to symptoms of a defensive nature, such as inhibitions in action, thought, and feeling and to perfectionistic or grandiose strivings.

Perhaps the most catastrophic consequence of lowered self-regard is the fostering of a profound disturbance in interpersonal relationships. The undermined person who harbors contemptuous attitudes toward himself is bound to have contemptuous attitudes toward others. Feeling unworthy and insignificant, he is prone to credit other people with malignant tendencies and poisonous attitudes directed at himself. He may strive to isolate himself from the world, little realizing that it is he who creates the conditions for his self-isolation. Furthermore, he is apt to develop strong feelings of resentment toward others on the basis that they reject him at the very time that he, himself, shies away from such intimacies as companionship, love, and helpmateship. An exorbitant need for affection and approval may coexist, but his feelings of unworthiness and his ideas of being unlovable act as impenetrable barriers. Indeed a warm feeling toward any other person may be a real threat. An intimate relationship may mean to him that he will lay himself open to criticism, exploitation, and even injury.

The feelings of resentment are usually too powerful to dissipate themselves and are often either projected outward toward the world in a diffuse paranoid reaction or are turned on the self in the form of agitated, depressed, and self-destructive tendencies. In the event that the character structure is such that rage and aggression are regarded as dangerous, the emotion may never actually penetrate into consciousness, but rather will drain itself off through autonomic channels, producing widespread adrenergic or cholinergic effects. In the event that the individual possesses a constitutionally defective organ, a psychosomatic disease process may be the final outcome.

A further consequence of a lowered self-regard is an unwarranted shyness, timidity, and submissiveness and a shrinking away from any situation that tends to arouse inferiority feelings. Manifold defenses will be set up against getting oneself into any situation in which one's inadequacy or inferiority may be exposed. This often leads to a general inhibition in intellect, a procrastination and postponement of endeavor, an inability to perform, a blocking of purposeful activities, and particularly a shrinking from competitive situations. The interference with work may be so extreme that the person may be unable to live up to his talents or aptitudes, and his timidity may remove the possibility of gratifying his fundamental needs, such as seeking a livelihood or a marital partner. His lack of confidence and self-assurance may be related to all situations or may be specifically related to performances with equals or superiors. The phenomena of stage fright, of inability to talk in public, and of stammering fall into this category.

The person with low self-esteem may feel so weak within himself that he is forced to cling compulsively to others for strength and sustenance. This leads to a dependency relationship with a stronger, more powerful individual and an unquenchable yearning for companionship, for special favors and attention which he may spurn even when proffered because of a feeling that he has no right to these favors. In some cases, self-contempt may be manifested as a masochistic drive with impulses toward self-punishment, self-injury, or self-destruction. These impulses are often unconscious means of purging oneself of guilt feelings or of restoring oneself as worthy in the eyes of authority. Punishment becomes then a commodity that secures for the individual retribution for actual or fancied transgressions. Projection tendencies may be associated with self-denial, and the patient, although exploiting himself, will hate the role he plays and blame the world for treating him like a doormat.

In the face of mounting tension and anxiety, relief is often sought in drink. Alcoholic indulgence may come to have a tremendous subjective value since by deadening the higher sen-

* This is the second of three papers on psychotherapy by Dr. Wolberg. The first paper appeared in the July 1 issue.—*Editor*

sibilities it releases the individual from the bonds of self-contempt. Alcohol becomes the magic carpet that sends him soaring into acts of intrepidity and feelings of self-importance. Under such circumstances sobriety becomes tantamount with suffering, surcease from which may be sought in bouts of drinking.

The psychodynamic core of devaluated self-esteem lies in the intense sense of helplessness and isolation that results from the discovery of self as an undermined, inept, inadequate, and contemptible person. As a result, any situation in which one feels worthless may precipitate choking sensations, heart palpitations, shakiness, blushing, sweating, and other symptoms of anxiety. There is a great vulnerability to slights, to criticism or disapproval, which in the setting of an over-evaluation of the opinion of others makes life a constant source of pain. There may be an inability to tolerate frustrations, however slight, because frustration is somehow looked upon as an indication of one's worthlessness. A physical illness or disease may similarly be looked upon as a positive proof that one is the loathsome person one fears himself to be, and individuals who regard illness as an assault on their status may have a lurking fear of syphilis or cancer or other corrupting malady in the form of a disease phobia that is peculiarly invulnerable to appeals to reason.

There is almost always an attempt on the part of the person with low self-esteem to project the inner devaluated image of himself onto whatever material situation exists that can provide objectivity for his basic feelings of inadequacy. These feelings may be symbolized by ideas that one has an inadequate physique or intelligence or bodily function. It goes without saying that the possession of a physical handicap, such as a facial blemish or an orthopaedic deformity, is often presented as reason for inner feelings of insecurity. Race, caste, and sex are other scapegoats, and there is often a tendency on the part of women to blame their neurotic problems on the fact that they are deprived of the privileges of men. An analysis of these objective conditions, even though they are realistic and undoubtedly foster insecurity, shows that they are merely façades which rationalize the contemptuous feelings that the individual harbors toward himself. Most physicians can provide examples from their own experience of individuals who, though suffering deforming or debilitating illness, feel sufficiently secure within themselves to succumb to neither panic nor anxiety, nor do they yield to the temptation of branding themselves pariahs without rights or privileges.

Most patients are only partially aware of the depths of their self-contempt, for the defensive forces of the ego frequently set up compensatory mechanisms to avert anxiety. A common defense is a complete repression of feelings of inferiority with a swing over to superiority strivings embracing compulsive drives for dominancy, mastery, and power. There is often associated an avoidance of relationships with superior or authoritative individuals and a seeking out of helpless and inept people. The patient may actually embark on a crusade of championing the helpless. In his attempt to help those weaker than himself there may often be detected a strongly aggressive attitude in the form of a desire to control others the way he himself feels controlled by authority. There may be strivings to attain those things symbolic of value in our culture in the form of prestige, status, money, lineage, or class distinction. Or the individual may try to adorn and bolster up his impoverished self by grandiose impulses. He may even develop a fabulous, bloated image of what he would like to be and live solely in the hope that someday this image will magically come into his own right. Beneath this narcissistic inflation, the physician will always detect a feeling of helplessness. One of the unfortunate consequences of the grandiose striving is that the patient may set up goals for himself that are superhuman in nature and which are impossible for any person to achieve. These goals are so high that failure is inevitable, and repeated failures light up the conviction of worthlessness, thus continuing the vicious circle of further grandiose strivings. In many instances shyness and timidity are completely repressed and a compensatory boldness drives the person into episodes that prove his strength and fortitude. The outward image he would like to present to the world is a creature of dauntlessness and braggadocio.

When strivings for mastery and power are signs to the individual that he is embarking on an aggressive role and where there is a fear of aggression, his desires for supremacy, for admiration, and appreciation may be indulged in merely in fantasy, either in the form of daydreams or in attempts to identify himself with great characters or outstanding personalities who possess the qualities he admires so intensely. There may also develop a tendency toward perfectionism, with a need to render oneself unassailable in all fields of work or play. There may result a concentration on the most inconsequential details of living that the average person would pass off as insignificant, as if any failure, however small, is evidence that one is utterly worthless and despicable.

How to deal with the entity of lowered self-

regard is a matter about which little agreement exists among the various schools of therapy. Logic tells us that if we dissect thoroughly the image that the person has of himself, if we teach him the destructiveness of this image, as well as the inadequacy of his defenses, he will change. That logic somehow fails is the experience of most physicians who are confronted with this problem in their patients. There is considerable danger in a premature probing of the contemptuous inner image of a patient. Mental stability is often maintained by a process of repressing the hideousness of this image, and when the patient is brought face to face with the basic feelings about himself the results may be disastrous. Similarly, one must attack with very great caution the various defenses that the patient has set up in the form of perfectionistic strivings, power impulses, grandiose desires, and the like, which are merely defense mechanisms enabling him to function in the face of his crushed self-esteem. There is little doubt that his defenses can be taken apart as irrational and exposed as impossible of attainment. An attack such as this almost inevitably creates panic because it arouses the specter in the patient of being the worthless and inferior person that he strives to avoid by his compensatory technics.

Another approach to the treatment of patients whose neurosis revolves about devaluated self-esteem is the analysis of the development of impaired self-strivings related to environmental experiences and conditionings. There is no question that genetic factors play a signal role in the evolution of the self as an entity. In the process of normal development the infant displays aggressive strivings which are perhaps biologically conditioned by the need to break from dependency ties with the parent. Curiosity and a certain amount of destructiveness in exploratory activities occur normally and the emotion of rage is precipitated whenever the child is hampered in his attempts at independent action. At the same time the child's physiologic helplessness makes him dependent upon his parents and causes him to react intensely to loss of parental love and approval. Where undue disciplines are used to crush the normal strivings for independency, where rage as it is expressed by the child arouses a threat of abandonment or of counteraggression, and particularly where the child feels unloved and insecure unless he conforms to the dictates of his parents without revolt, the normal desire for independence and the normal exercise of aggressiveness will have to be repressed. Furthermore, a series of defenses may be set up with the aim of keeping aggression in check.

The domineering type of parent who considers the child's aggressiveness and striving for independency a threat to himself may crush the child into a state of compliance and interfere with the normal development of the ego. As a result, the child may never attain to a state where he can emancipate himself from the parent, and he may never develop proper feelings of self-sufficiency, self-reliance, and self-confidence. He is apt to become dependent for his self-evaluation upon others rather than upon himself, and he is prone to rely completely on the standards, values, and ideals of other individuals. The parent who deflates or humiliates the child by telling him that he looks or acts stupid, the parent who subjects the child to beatings or who sets goals and standards for the child far above what can be expected of him in view of his intellectual and experiential immaturity also sows seeds for a devaluated image of the self. Strong sibling rivalry in the event of an older child who sees his parents transfer their love and attention to a newcomer is another condition that is seen with great frequency, especially in a child who feels insecure in his relationships with his parents. Such a child may interpret the transfer of love to the younger child as a sign of abandonment and an indication that there is something wrong with himself. Also a younger child who is unable to attain to the performances of an older sibling and who is whipped up into a frenzy of competitiveness by goading parents or relatives is also apt to develop inferiority feelings.

It is true in some cases that an analysis of the determinants in the child-parent relationship may start a curative process going, but unfortunately this does not happen nearly so often as one might expect. Usually a search for causation yields little except that it provides the patient with a chance to pass responsibility for his problems on to the parents. In this way it gives him an opportunity to rationalize his possibilities for change on the basis that it is too late for him to do anything about the way he was reared.

The question that often arises is whether rebuilding the self-esteem would not dissipate the neurotic symptoms and the defensive coping devices that issue from the feelings of helplessness. There is little doubt that were we able to rebuild devaluated self-esteem in a patient the effect would be ameliorative if not curative. The important problem is the technic by which the self-esteem can be restored.

Reassurance and praise are devices as old as psychotherapy itself and are based on the theory that if we inflate the patient's ego he will resurrect himself from his plight. Unquestionably there are some individuals who respond almost miraculously to therapy of this type. When we

analyze the character structure of these patients we find that they are usually compulsively dependent individuals who have established a relationship with the psychotherapist through which they yield themselves completely to his opinions and demands. In a situation such as this, the individual's self-esteem is based on how well he believes he is regarded by the therapist. Reassurance in this type of patient will certainly restore his self-esteem. This, however, is only temporary, for the self-esteem will be maintained only so long as there is confidence in the protective and magical properties of the therapist. Unfortunately the dynamics of the dependency relationship are such that intense feelings of hostility generate themselves when whims and fancies are not fulfilled by the magical protector. The patient's demands eventually become inordinate, and his hostility at not having his demands fulfilled may become so intense that the relationship will terminate explosively. The patient will then embark on a quest to find stronger and more generous hosts.

In some instances patients will actually be plunged into panic by reassurance and praise on the part of the physician. The basis for this anxiety is often the exorbitant expectations that the patient has of himself and the secret wish to attain to extraordinary accomplishments. The fear of failure so frequently encountered may stem from a twofold cause: first, the coming face to face with the inadequate, contemptible image of the self in failure, and, second, the discovery that one's abilities and potentialities are no more than merely human. Such patients are unconsciously arrogant to an extreme, and while they overtly flagellate themselves with their inadequacies, secretly they expect and hope that others will detect in them superhuman qualities. Reassurance precipitates rage and despair, for the patient feels that the physician is satisfied with him the way he is and threatens to dissolve the image of what he would like to be before his very eyes. Under such circumstances the physician may be rejected as incompetent or hostile.

Another reason why praise and reassurance may fail is that the entire structure of self-devaluation may serve a vital purpose of protecting the self from injury or may act as a means of pleading for love and protection on the basis of one's helplessness. This is often the case if the patient as a child got security from his parents through submission or if the undermining of the self became a condition essential to being loved. As a result, any attempt to assure him that he is not a helpless, inadequate individual may threaten to remove an important protective mechanism. There are some patients who actually capitalize on the low opinion of themselves, seeking opportunities to tear themselves down, thereby gaining vicarious pleasures. In addition to the masochistic yielding to suffering as penance for forbidden impulses or fantasies, some patients use self-debasement as a means of excusing themselves from activities and interests indulged in by normal people. If one is inept and helpless one may be excused from relating himself emotionally to other persons. Here unconscious fears inhibit the individual from expressing sexual and social needs, and the low self-esteem is used as an escape mechanism. This mechanism the patient will hold onto in spite of praise or reassurance.

Other methods of rebuilding self-esteem are perhaps more efficacious. Among these is occupational therapy. A skilled therapist can often turn many of the patient's frozen energies that have been inhibited by a fear of failure into creative channels. When the patient's expectations of himself are not too exorbitant, it is possible that his entire estimate of himself may be rebuilt by activities along a creative line. The process is necessarily a long one since it involves a rebuilding of self-confidence and a feeling that one can function independently without the need of a magical protector and without the fear of being injured for what he considers to be aggressiveness on his part. Occupational therapy and the externalization of interests into such channels as hobbies, welfare work, and social activities may, by adding to the self-esteem, permit the ego to proceed to a more or less complete repair.

The tenacity with which patients cling to the devaluated image of themselves is always confounding unless we analyze the character structure to determine what the patient symbolically believes his self-esteem is based upon. Only by analyzing these symbols can we deal effectively with the structure of his diseased regard of self. For example, a compulsively dependent person measures his self-esteem in terms of whether he is loved or approved of by the person upon whom he leans. The individual whose personality is one of aloofness and self-sufficiency will regard himself with contempt when he accepts help from another person. His self-regard is based upon a need to maintain his individuality, which in turn generates strivings to ward off those intimacies that encroach on his privacy. To accept help or love or advice from another is to him a sign of weakness. The perfectionistic individual suffers a shattered self-esteem whenever any of his thoughts or acts are in any way imperfect or assailable. The self-esteem of the narcissistic individual is based upon how much he is admired and praised by others. The self-regard of the

compulsively ambitious person is proportionate to his material achievements. The neurotic who has an unquenchable thirst for power is secure only when he is strong and invulnerable and when he dominates and controls others. The compulsively modest soul is secure within himself only when he makes himself inconspicuous. It is apparent that unless we know the determinants of the patient's self-esteem we may be unable to help him overcome his problems.

Whether or not a deep analysis is necessary in all cases is open to question. There are some persons borderline to psychotic whose egos may be unable to tolerate the powerful emotions released by analytic therapy. On the other hand, deep unconscious modes of mental functioning may express self-devaluation in terms of primitive symbolism, as, for instance, in terms of phallic loss or possession. Deep fantasies may involve a fear of emasculation in the male and a contempt for femininity in the female, and there may be attempts to restore a fancied damage to oneself by various rituals, compulsive phenomena, and physical symptoms whose meaning can be understood only when their symbolism is translated.

Perhaps the best tool available for the rebuilding of self-esteem is the interpersonal relationship that develops between the physician and patient during the therapeutic process. In this the patient lives through the drama of his attitudes toward himself and others and is provided with insight into how he functions while re-experiencing his customary patterns of behavior. During treatment the patient learns the dynamic function of this low self-regard as well as the defensive devices he employs to protect himself from his helplessness. Psychotherapy is most effective when it ceases to be a pallid intellectual process in which the physician attempts to enlist the logic of the patient to explain away his symptoms. Rather, it is through the emotional experience of the patient's relationship with another human being, who happens to be the doctor, that the patient reorients himself to the world and rebuilds his attitudes toward himself. Self-esteem is so inextricably intertwined with the entire character structure that an analysis of the personality in operation as it functions in the therapeutic relationship is an almost indispensable condition in the process of cure.

Summary

During psychotherapy it may become apparent that the central neurotic process is a tremendously devaluated self-esteem, of which the patient is only partially conscious. This diseased attitude toward the self sets into motion defensive devices such as detachment, manifold inhibitions, inordinate dependencies, masochistic, paranoid, and grandiose strivings. How to rebuild the patient's devaluated self-esteem becomes a problem of vital importance. Therapeutic attempts aimed at exposing the depth and destructiveness of the patient's contemptuous image of himself may be both ineffectual and dangerous. Similarly, removal of his protective devices, such as his dominancy, power strivings, and needs for perfectionism, may precipitate panic, for they are defensive mechanisms which shield him from helplessness and isolation. A probing of the genetic determinants which have produced his helplessness may accomplish little other than to provide him with a scapegoat on which he can shift responsibility for his condition. Reassurance and praise frequently fall short of their therapeutic goal, and attempts to acquaint the patient with the fact that he is not so contemptible as he had supposed and therefore need not employ his neurotic protective devices are usually without benefit.

The most potent therapeutic device available is the emotional experience that develops in the interpersonal relationship between the physician and patient. In this relationship the character structure of the patient unfolds itself and the symbols by which he measures his estimate of himself are analyzed as he experiences them actively. The extent of the re-evaluation of the self occurs in proportion to the ability of the patient to gain insight into his character structure and his ability to reorient himself to others during the experience of his relationship with the physician.

HYPERTENSION AFTER FORTY

On the basis of blood pressure readings on 14,849 persons over 40 years of age, Commander A. M. Master (M.C.) USNR; H. H. Marks, A.B., Bethesda, Maryland; and Captain Simon Dack (M.C.), Army of the United States, report in the *Journal of the American Medical Association* that they believe "The presence of hypertension at age 40 and over is so common that a mild degree and perhaps even a 'moderate' degree can no longer be considered abnormal. Limits of normal blood pressure at these ages should therefore be raised. . . ."

PSYCHIATRY IN A GENERAL HOSPITAL

C. P. Oberndorf, M.D., New York City

At a dedication in the fall of 1941 of the new buildings of a mental hospital devoted primarily to the care of recoverable mental cases, one of the speakers advanced the idea that more hospitals of this type would obviate the necessity in the future for huge institutions devoted to the care of the chronically mentally ill. The hope for the prevention of mental disease, however, rests not particularly in hospitals where hopeful forms of mental disease are treated, but far more specifically in agencies in closer and more direct contact with the whole population than any hospital for psychiatric cases can ever be. I refer to common and collegiate schools, general hospitals, and particularly to outpatient psychiatric clinics where emotionally disturbed and confused persons, still active and attempting to carry on their life tasks, are first seen.

Universality of the Psychic Function in Disease

Before the days of intense specialization, which we can date from the beginning of the present century, the family physician treated a person afflicted with any form of disease and was likely to care for the same patient many times during his life, attending all his illnesses from birth to death. Through these frequent contacts he knew many characteristics of his patient's psychic make-up, many facts bearing upon his immediate and past social difficulties, and the most important influences of heredity and environment to which he had been subjected from childhood. Through this he had learned how the patient as a person met physical injury, personal loss, or reacted to an infectious disease.

The necessity for expert skill in diagnosis and operation fostered the tendency toward specialization, but the specialist no longer observed the patient in a sickroom that reflected his own personality, and perhaps also the personality of his forebears. Often he saw him for the first time in a hospital bed divested of all significant elements including even his normal manner of dressing. The physician thereby lost valuable aids in planning the treatment. To be sure, he might detect, or learn from interns or nurses, that the patient was of the apathetic, stubborn, dull, uncooperative, anxious, or restless type. But even a most painstaking history by the average intern would not be likely to indicate what manner of man had a broken leg or a pneumonia.

Furthermore, the visiting physician of a hospital who supervises the treatment on the wards often of necessity sees relatively little of the patient after a satisfactory diagnosis has been established and treatment has been outlined. Only when some acute situation arises which redirects his attention to the medical problem does he again study the patient as a person. To a lesser degree this applies to private patients in hospitals—especially surgical cases. This notwithstanding, people who are patients in hospitals have the same peculiarities and needs for individualization that the family doctor learned to consider through long contact.

The Scope of Psychiatry

To what extent is it possible for still another specialist, the psychiatrist, in this plethora of specialists successfully to approach this person-patient in the general hospital isolated from his emotional attachments? Hocking, in his recent essay, remarks: "The psychiatrist is the embodiment of applied science, attempting to deal with the ravages of the mistakes of science. What he finds is that more science is not enough."[1] As a rule, the psychiatrist's services are called for only when the refractory or apathetic attitude of the patient is obviously interfering with the success of therapy, or when recognized procedures have failed to establish a satisfactory diagnosis.

The psychiatrist begins his work under a handicap because the environment of the ward is so mechanical that the patient becomes a part of the iron bed on which he lies. This is reflected in such terminology as "Bed 6 has a Ca." To be sure, the human element is often effectively introduced through the nursing and the resident staff or, in a few hospitals, through the social service interview. However, the emphasis in the training of the nurse and intern in the general hospital has usually been put on physical procedures and physical methods. It is therefore difficult, with the heavy preponderance of interest in physical procedures, for instructors in psychologic medicine to convey the idea that psychiatry is essentially concerned with the emotional constitution of the patient and his subjective reactions. So it is understandable that when a student physician or nurse first hears

Author's Note: Elaborated from a lecture delivered at the New York Psychoanalytic Institute on April 24, 1942. The observations are based upon more than twenty-five years' experience at Cornell University Clinic (1909–1922), Bellevue Hospital (Second Division, 1914–1922), and at Mount Sinai Hospital and the Out-Patient Clinic of Mental Health (1913–1939).

of dementia praecox, his previous conception of diagnosis makes him regard this condition as a disease which the patient has acquired, as he might acquire the mumps, not as a condition which is essentially the person.

It is customary for every good physician to take into consideration some of the elements called neurotic or psychotic which complicate physical conditions. Without recognizing them he could not be a good physician. The best physicians possess a strong, highly intuitive, common sense evaluation of certain emotional forces working with or against their medical and physical procedures. However, without some knowledge about the mechanisms which are operating, the physician's intuitive evaluations cannot carry him very far in the management of neurotic conditions, the depressions, or the negativism that complicate disease.

Most practitioners will agree that a large proportion—perhaps three-quarters—of their daily practice consists of treating patients with complaints due to dissatisfaction with life. These complaints are referred by the disgruntled person to various organs of the body, most frequently as headaches, gastrointestinal disturbances, or cardiac dysfunction. The reassurance of the patient by his doctor, in whom he has confidence—or, in psychoanalytic terminology, "to whom he has a positive transference"—often suffices to allay temporarily the dissatisfactions converted into bodily complaints, the "sick and tired feelings," or "faint heart." Many of these patients can be treated only by accepted remedies and would scoff at the suggestion that their stomachache represented a psychologic "belly-aching." On the other hand, the average physician is reluctant to admit the limitations and inadequacy of his therapeutic skill and may continue to treat on a physical basis symptoms which he may suspect to have a strong emotional content—sometimes for fear of offending his patient.

Transference in a Hospital Ward

In the patient-doctor relationship with the family doctor, a certain degree of confidence is gradually established. Perhaps the very choice of the particular doctor, when there is more than one in the town, indicates an empathy which the patient has for that physician. This may be for one of many reasons, but the two most obvious and frequent would be an identification of the physician with a firm, dependable father, or a good, sympathetic mother.

In the unconscious, almost every illness, even a broken leg sustained in an automobile accident, is associated by the patient with a feeling of punishment. It is often accompanied by an unexpressed feeling of guilt and a search for the moral cause of the punishment. The physician becomes an agent, paternal or maternal in pattern, who can be relied upon to absolve as well as to heal. Patients with deep religious convictions may invest the hospital of their faith, the Sacred Heart, Baptist, or Israel, with additional potentiality for cure, absolution, redemption.

However, the patient's choice of a hospital, when there is a choice, is based upon confidence in a relatively abstract idea of a group. "The ——Medical Center is a good place." Here the confidence resides in a concept of strength and power rather than in a single living person with human interest. Although confidence in the hospital may be strong, there can be no direct evidence of sympathy and reassurance from the hospital to the patient comparable to that of human interplay. This the patient always consciously or unconsciously expects and usually receives from the private physician of his choice. To obtain such needed reassurance the hospitalized patient may unconsciously exaggerate his symptoms based on physical pathology, following the mechanism of secondary gain through illness, to satisfy an urgent need for attention.

Thus the psychiatrist who approaches the patient in the environment of a hospital public ward is handicapped by the fact that the primary transference has already been made to the abstract concept of a group of which he, the individual physician, is a comparatively minor force. The constant impact on the patient of the multiformed forces of this hospital environment makes extremely difficult any establishment of a strong transference to the psychiatrist. In addition, the psychiatrist cannot avoid having the little positive transference remaining with the patient become diffused among the various individuals with whom the latter comes in contact.[2]

Other conditions also tend to make the psychologic approach to the hospitalized patient troublesome. For instance, even the most intelligent person has a desire for the quickest form of relief from his suffering. This wish, in persons whom one would least suspect, may be deep and urgent and may take the form of a hope for the magical disappearance of the illness. The faith in magic is psychologically closely associated with confidence in the powerful father or indulgent mother, but the element of animism is also included in it. During the centuries, such primitive animism gradually became associated with pills and medicines, and later with surgery, electricity, radium, complicated-looking apparatus, etc. At the moment, magic resides in vitamins.

A patient in his iron bed, whose symptoms are primarily neurotic but who sincerely regards

them as physical, generally has a belief in and a desire for some magical cure beyond that which the average patient expects. He is prone to be envious of any elaborate treatments which other patients receive. Unless he has become disappointed in the failure of these physical ministrations to produce results or is beginning to feel that his worries may have caused his physical troubles, he is not likely to be ready for and to welcome the new physician with a psychologic approach.

Even though the patient is fairly receptive to a psychiatric approach and the psychiatrist does make some impress, he still remains subject to influences which tend to hinder the psychiatrist's aims. Quite unwittingly, the interns and nurses may make remarks that indicate to the patient that what he needs is another metabolism test, a different type of colonic irrigation, a new sedative or hypnotic.

Also, the privacy of a strictly personal conversation is difficult to maintain behind bed curtains. The patient becomes restless, wary, and self-conscious, thinking that the occupants of adjacent beds are listening. For satisfactory work the psychiatrist is entitled at least to a consultation room in which his investigation into a patient's emotional problems can be carried on in quiet and at leisure. Every type of neurotic or psychotic patient finds his way into a general hospital either because of his psychic condition or because of some definitely physical affliction. Hence, a necessity exists in any large hospital for a few private rooms where sensitive, neurotic patients can be temporarily isolated for study.

When the nature of the emotional problem has been determined and the symptoms are found to be preponderantly psychologic, the patient should be transferred as soon as possible to the outpatient clinic for further treatment.

One of the most discouraging aspects of psychiatric work in a general hospital is the fact that it frequently cannot be continued for any length of time. The main cause for this is the necessity of vacating the bed as soon as the patient is sufficiently well to leave the hospital. Another frequent reason for discontinuing the psychiatric work is the need which the patient may develop for intensive medical or surgical treatment because of some intercurrent affection. The psychiatrist may have spent several hours obtaining certain social and personal facts, but when the patient is transferred to the department which his predominant symptom indicates, this information becomes almost useless because the patient's contact with the psychiatrist ceases. This is not only a waste of time for the psychiatrist but often conditions the patient against future psychiatric approach. Such psychiatric work is a frequent occurrence. It is comparable to scrubbing up the skin of a patient for an operation which never occurs, and many patients with psychiatric problems are easily rubbed raw.

Psychiatric Therapy in Outpatient Clinics

The effectiveness of an outpatient clinic depends first and foremost upon leadership and personnel. One may then say that the personnel depends upon the leadership, for without vigorous, continuous, and imaginative leadership such a clinic soon falls into a monotony of routine which eventually is reflected in perfunctory care and desultory interest in the patients.

For effectiveness in all psychiatric therapy, whether in private practice, clinics, or general or psychiatric hospitals, there must be a continuity in treatment and in philosophy of approach. By this I do not mean to say that there is only one philosophy of approach, such as suggestion, persuasion, discipline, or psychoanalysis with its emphasis on mechanisms and the unconscious. Nor is any one philosophy adaptable to all patients. In general, it must be the function of an outpatient clinic as a whole, and of each individual physician, to give the patient reassurance and support, especially at the beginning of the contact, regardless of what the psychiatric disorder may be.

If it is true that such continuity and support are essential, then it is evident that for the therapy to be effective the same clinic physician should be available to the patient at not too infrequent intervals. Both private and clinic experience indicate that for most cases a visit three times a week is sufficient to meet the needs at the beginning of treatment or during acute phases arising later. Subsequently, the frequency of visits may be tapered off.

Sometimes the transfer of a patient from the hospital to the outpatient clinic should not be made directly. Often it is inadvisable to do this because he must return to a disturbing situation in his home. This is particularly the case if the patient is still in need of moral support or quiet housing. For such neurotic and prepsychotic patients, a special boarding or nursing home in the city is needed—a "half-way house." Such a home would surely protect many patients against going further on the way toward a closed mental hospital. These patients would be drawn not only from those who had been previously observed in general hospital wards but would also include the ones who frequently apply directly to the outpatient department for treatment. Other patients would be persons who are not imminently threatened with psychotic disorders but who nevertheless cannot or should not be

cared for in their own homes because of the symptoms of their neurotic illness. The house should have facilities for group activities, occupational therapy, and recreation, and the general atmosphere should be conducive to reassurance and regularity.

Patients would be permitted to go to work or to vocational workshops, actively help in the care of the house, etc. This idea is not new. It has been in actual operation in large converted houses in Leningrad and, more elaborately, years ago at a home in Zehlendorf, near Berlin. The patient's psychiatric treatment initiated at the hospital or clinic would be continued in the outpatient department of the hospital where he was originally observed, and preferably by the physician who made the first contact. With the benefits of a boarding home the scope of the treatment of outpatient clinics could be extended further and further in its function as an outpost against the threat of severe mental disease.

In outpatient clinics it is possible at relatively little expense to construct small cubicles or rooms where the psychiatrist can establish a confidential relationship with the patient. Most patients in a psychiatric clinic are likely to come expecting medicine or physical implementation. Often only indirect psychotherapeutic methods of approaching the patient are effective, for it is not easy to convince those habituated to diets and medicines that their disease is functional. The psychogenic origin of the symptoms can be established and accepted by the patient only in a minority of cases.

Treatment must be largely re-educational, persuasive, and supportive, re-enforced by a social service department that is ready to help the patient to complete the physician's suggestions and that is not above offering financial aid in cases of need. Although Benjamin Franklin said it years ago, it is still extremely "difficult for an empty bag to stand upright." I might add that unless each bag is filled with something more substantial than psychoanalytic interpretation it will seldom make an effort to stand erect but will go elsewhere to be filled—even with rubbish.

Occupational therapy in the outpatient clinic is of value not only as a direct curative agency but also as a socializing center. I believe that it would be found correct, if one were to question the patients, that they often attend the occupational therapy room not for the baskets they weave or the brass they hammer but primarily to meet other people and to escape from the tension of their homes. This is understandable, for in most homes a neurotic person is something of a nuisance, and in that home is usually to be found the irritating influence, a person or a situation, which has kept the neurotic's complaints alive and active.

Extension of the social influence of the clinic can be made through the establishment of clubs for patients. An interesting experiment at the Outpatient Clinic of Mount Sinai Hospital has indicated that many patients who are handicapped either intellectually or emotionally much prefer association with people of their own level with whom they feel on a par than with others better adapted socially with whom they feel inadequate and excluded.[3]

Psychoanalytic treatment can profitably be given in an outpatient clinic in selected cases when the person harboring the neurosis is intelligent, not too old, and when the home and occupational situation permit him to come regularly three times a week for at least three-quarters of an hour. I have seen good results obtained in such cases where the analyst was competent and the patient was adapted to his treatment. However, it is futile to attempt to convey to the average clinic patient psychoanalytic dynamics which must appear to him very bizarre and confusing, and which usually are slowly accepted by the most intelligent private patients who visit the analyst five times a week.

The psychiatric clinic should serve as a temporary anchorage for those patients who are emotionally and mentally adrift, and, when properly conducted, it does. The pilot for each patient is his individual psychiatrist, who ideally should see him through the voyage of illness to the harbor of cure.

TREATMENT OF ANGINA PECTORIS BY TESTOSTERONE PROPIONATE

Louis H. Sigler, M.D., and Joseph Tulgan, M.D., Brooklyn

WITHIN the past three years some reports have appeared in the literature stating that symptoms of cardiovascular disease can be relieved by testosterone propionate* given intramuscularly. The first to call attention to the beneficial effects of this hormone on vascular disease were Edwards, Hamilton, and Duntley[1] in 1939. They found by spectrophotometric study that there was a lack of arterial blood supply in the skin of castrated men. If such patients are given testosterone propionate, the blood supply to the skin increases. They also observed beneficial results of this product in 3 cases of Buerger's disease and in 4 cases of arteriosclerosis, all of which had intermittent claudication. The claudication was either greatly diminished or entirely abolished, and the peripheral blood supply was improved.

In 1940, Walker[2] reported beneficial effects of this hormone, as well as of other sex hormones, not only in peripheral vascular but also in cardiac disease. The anginal syndrome was greatly improved, and there was an increase in exercise and emotional tolerance. He even claimed to have observed relief from paroxysmal nocturnal dyspnea, and signs of improvement in the cerebral circulation. He suggested, however, that the psychotherapeutic effect of the injection might have been responsible for some of the beneficial effects.

In 1941, Bonnell, Pritchett, and Rardin[3] reported beneficial effects of estrogenic and androgenic substances in 23 cases of angina pectoris. They cited experimental evidence to indicate that all sex hormones have a vasodilating effect on the coronary vessels, which produces the beneficial results.

This was followed in 1942 by reports of Lesser[4] and Hamm[5] on the beneficial effects of testosterone propionate in angina pectoris, and of Walker[6] on the beneficial effects of this hormone as well as of estrogenic substances in all manifestations of cardiovascular disease. The last author also observed a drop in blood pressure in cases with hypertension, and many other symptoms due to disturbances caused by cardiovascular disease were relieved.

We carried out observations on the effect of testosterone propionate in 20 cases of angina pectoris, and feel that the results are encouraging enough to warrant this report.

Selection of Cases and Procedure

The patients selected were men, varying in age between 40 and 65 years, exhibiting unmistakable evidence of the anginal syndrome in a rather marked degree. Twelve cases had at least one episode of coronary occlusion, and several of these had two or three such episodes within a period of one to five years previous to our observations. All cases showed a markedly hyperactive cardio-inhibitory carotid sinus reflex, previously described by one of us,[7,8] which was used as one of the criteria of the presence of coronary disease. Twelve cases showed definite abnormalities in the electrocardiogram.

The anginal syndrome in all the cases was precipitated by comparatively slight exertion and by emotional upset. Many of the patients could not walk more than one block without the use of nitroglycerine. The injections were given in doses of 25 mg. of testosterone propionate dissolved in sesame oil, twice weekly.

To rule out as far as possible the psychotherapeutic effect of the injection itself, regardless of what the product might be, a control was used in 6 cases. These patients received injections of the testosterone propionate in sesame oil for a period of about four weeks, alternated by a similar period when only sesame oil was used. The ampules all looked exactly alike and the patient was not aware of what he was getting. In some of these cases the testosterone propionate injections were again resumed after sesame oil alone was used over a certain period.

Observations

There was unmistakable evidence of symptomatic relief from the anginal syndrome in 11 cases. The precordial pain greatly diminished, and there was a feeling of well-being. Patients who could not walk more than one block before without the use of nitroglycerine were able to walk many blocks without resorting to the use of this drug. In 5 other cases the response was less spectacular, but the patients nevertheless appeared to have had some relief. They could walk a greater distance than before without the use of nitroglycerine. In 4 cases no relief whatsoever was obtained.

Relief from symptoms, when present, con-

From the Cardiologic Service, Department of Medicine, Coney Island Hospital, Brooklyn, New York.

* The testosterone propionate used in this study was kindly supplied to us by the Ciba Pharmaceutical Products, Inc., Summit, New Jersey, under their trade name of Perandren.

A B

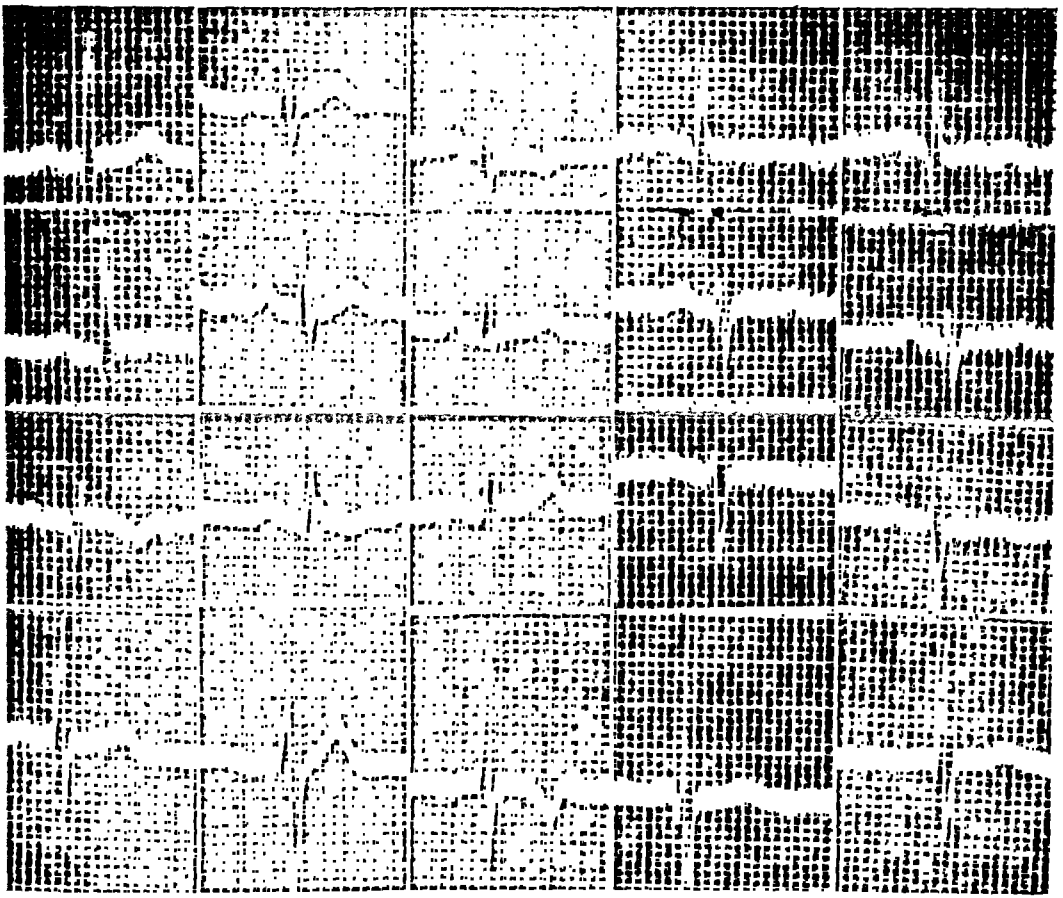

FIG. 1 FIG. 2 FIG. 3 FIG. 4

tinued as long as the testosterone was used, and in some cases persisted for about two to four weeks after the medication was discontinued. The symptoms then returned with increasing intensity until they became as severe as they were before the treatment was started.

Although symptomatic relief was definite, objectively no changes were observed in the physical and electrocardiographic findings. The size of the heart, its rate, rhythm, and sounds remained about the same. The hyperactive cardio-inhibitory carotid sinus reflex was not diminished. There appeared to have been a tendency to a reduction of the previous average blood pressure level. In view, however, of the marked spontaneous fluctuations in blood pressure in many cases, as shown by one of us,[9,10] we are not sure that the average lower blood pressure level observed under testosterone propionate therapy was due to such treatment.

Because of the striking difference in response to testosterone propionate as compared with that to plain sesame oil in the control group, we are presenting this group in more detail.

Case Reports

Case 1.—A 50-year-old man complained of severe precordial pain after walking as little as three to five blocks and after a heavy meal. The condition followed an attack of acute coronary occlusion three years before and was getting progressively worse. Only nitroglycerine gave temporary relief.

The physical examination showed slight enlargement of the heart to the left, the rate was 60 to 72 per minute, and the rhythm was regular. The first sound was diminished in intensity, and the second sound was accentuated. There was a moderately

hyperactive cardio-inhibitory carotid sinus reflex. The peripheral blood vessels were markedly sclerotic, and the blood pressure was 140 to 150 systolic and 80 to 96 diastolic on different occasions. The electrocardiogram (Fig. 1) shows an iso-electric T wave in the second and a negative T wave with a large Q wave in the third lead. These are undoubtedly the remains of a posterior left ventricular infarction.

The patient received 25 mg. of testosterone propionate twice weekly. After the third injection he showed marked symptomatic relief. He could walk 2 or 3 miles without discomfort. The injections were continued for about six weeks. During this period the pain occasionally recurred in a mild form after considerable exertion.

The testosterone injections were then stopped, and the patient was told to return to the clinic if severe pain returned. He came back about five weeks later when the pain became severe again, and he was then given plain sesame oil injections twice weekly for a similar period, with no relief from symptoms.

During the time that he received the testosterone, no changes were noted in the physical findings, and the blood pressure was 110 to 140 systolic and 80 to 90 diastolic.

Case 2.—The patient, a man 46 years old, was under observation at the clinic for a period of six years. He complained of recurring retrosternal pain radiating to the left elbow and forearm, which came on after he had walked four or five blocks.

The physical examination showed nothing abnormal in the heart except for some muffling of the first sound. A teleroentgenogram showed the heart and the great vessels to be normal. The electrocardiogram (Fig. 2) showed some slurring of the QRS complex, and the voltage of this complex in the 3 conventional leads was within the minimum limit of normal. The peripheral vessels showed slight sclerosis, and the blood pressure was 90 to 120 systolic and 56 to 80 diastolic. He had a moderately hyperactive cardio-inhibitory carotid sinus reflex.

The only medication that gave him relief was nitroglycerine. Many other medications were tried without definite relief.

He was given sesame oil injections for about six weeks, twice weekly, without relief of symptoms. He was then given testosterone propionate injections for three weeks, twice weekly, without noticeable change in symptoms. The pain continued practically the same as before.

Case 3.—A man, 42 years old, complained of precordial pressure radiating to the left arm and dyspnea on walking one or two blocks. These symptoms were of one year's duration and were relieved by rest and nitroglycerine.

The heart was of normal size, the rate was 65 to 84, the rhythm was regular, and sounds were of good quality with accentuation of the second sound at the aortic areas. There was a markedly hyperactive cardio-inhibitory carotid sinus reflex. The blood pressure was 140 to 150 systolic and 80 to 90 diastolic. The electrocardiogram (Fig. 3) shows left axis deviation, slight depression of the QRS-T segment in the first and elevation in the third lead and negative T wave in the first and fourth precordial leads.

He was given fourteen sesame oil injections within a period of seven weeks with no improvement in symptoms. Testosterone injections were then given in doses of 25 mg. twice a week. After four injections the patient had greatly improved and was practically free from symptoms for a period of seven weeks during which he received this therapy. The physical findings, however, remained unchanged and the blood pressure was 100 to 120 systolic and 70 to 84 diastolic.

Case 4.—A 54-year-old man complained of severe cramp-like precordial pain radiating to the left arm, with dyspnea, and dizziness. The symptoms appeared after the slightest exertion—such as walking two blocks—and were getting progressively worse within a period of one year. Nitroglycerine was the only drug that gave temporary relief.

The physical examination showed moderate enlargement of the heart. The rate averaged between 70 and 84 per minute, and the rhythm was regular. The first sound at the apex was moderately diminished, and the second aortic sound was accentuated. There was a markedly hyperactive cardio-inhibitory carotid sinus reflex. The peripheral blood vessels were moderately sclerotic, and the blood pressure was 160 to 190 systolic and 100 to 110 diastolic. The electrocardiogram merely showed left axis deviation.

The patient received 25 mg. of testosterone twice weekly. After two injections the symptoms were greatly relieved, and after the third the patient had hardly any pain on exertion. He claimed that he felt better than he had in the past three years. He could walk a mile or more without resort to nitroglycerine and without pain. The physical findings remained the same, however, and the blood pressure was 134 to 180 systolic and 90 to 110 diastolic.

Following sixteen injections of testosterone, we switched to sesame oil injections twice weekly. Three weeks after the last injection of testosterone and while continuing the sesame oil, the patient stated that he again had considerable pain which became progressively worse as the sesame oil injections were continued.

Case 5.—A man, 64 years old, complained of squeezing pains in the precordial region radiating to both arms and fingers, appearing on the slightest exertion, and even at rest. He had been forced to stop work four years before. On two occasions two years apart, he was hospitalized because of the severity of the pain. Only nitroglycerine gave temporary relief, and he was in the habit of taking 8 or 10 $^1/_{100}$-grain tablets daily.

He had moderate enlargement of the heart. The rate was 62 to 78 per minute, and the rhythm was regular. There was a systolic murmur at the apex and the sounds were accentuated. The cardio-inhibitory carotid sinus reflex was markedly hyperactive. The peripheral blood vessels were grossly sclerotic, and the blood pressure was 100 to 140 systolic and 70 to 80 diastolic. His electrocardiogram showed merely left axis deviation.

After he received two injections of 25 mg. each of testosterone propionate the first week, the pain greatly diminished. As the injections were continued, the patient was able to walk from the trolley to the hospital, about four long blocks, without the aid of nitroglycerine. Formerly he had had to stop three or four times on the way and had had to resort to the drug each time to get relief. He was also able to sleep through the night without being awakened by his pain. The physical findings remained unchanged during this period and the blood pressure was 110 to 130 systolic and 70 diastolic.

After fifteen injections of testosterone he was given sesame oil injections twice weekly. Four weeks after discontinuing the testosterone, he had a recurrence of precordial pain which gradually grew worse, and he again had to resort to nitroglycerine and a great deal of bed rest.

Case 6.—A 50-year-old man complained of pressing pain in the precordium which occurred on exertion and at rest, with dizziness of three years' duration. None of the ordinary medication gave relief.

His heart was of normal size, the rate was 72 to 80 per minute, and the rhythm regular. The first sound was diminished in intensity and the second accentuated, A_2 being of ringing quality. There was a moderately hyperactive cardio-inhibitory carotid sinus reflex. The peripheral blood vessels were markedly sclerotic and the blood pressure was 130 to 180 systolic and 80 to 90 diastolic. His electrocardiogram (Fig. 4, Section A) shows left axis deviation and a very low voltage T wave in the three conventional leads. Section B, obtained six weeks after A, during the testosterone propionate therapy, appears to show slight improvement in the T wave. The changes, however, are of insufficient degree to be given significance.

He received 25 mg. of testosterone propionate, twice weekly, over a period of seven weeks. During this period he was free from pain. Relief came after the third injection. The patient was able to walk as much as a mile without discomfort. He was also able to do a great deal of work around his home without pain. His blood pressure varied from 110 to 175 systolic and 60 to 80 diastolic during this period, but no other changes were noted in the physical findings.

The injections were then discontinued, and the patient was told to return when pain recurred. He has not returned to the date of this writing, about two months later.

Case 7.—The patient, a 57-year-old man, complained of severe pressing precordial pain for two years, which was present at rest and became worse on exertion. Temporary relief was obtained only with nitroglycerine.

His heart was of normal size, the rate was 80 to 84 per minute, and the rhythm was regular. There was a systolic murmur at the apex and aortic area. The first sound was diminished, and the second aortic sound was accentuated. There was a markedly hyperactive cardio-inhibitory carotid sinus reflex. The peripheral blood vessels were markedly sclerotic and the blood pressure was 140 systolic and 70 to 80 diastolic. The electrocardiogram was normal.

He received 1 cc. of sesame oil twice weekly for seven weeks. There was little change in his symptoms although now and then he claimed to have had some relief. It must be remarked, however, that during the entire period in which he received these injections he did not work and rested most of the time. Whatever relief he experienced might well be due to this cause, as well as to the psychotherapeutic effect of the injection. His blood pressure varied from 90 to 130 systolic and 70 to 75 diastolic during the injections.

Comment

To evaluate any medication in the treatment of the anginal syndrome we must consider various factors that may influence its symptomatology. Relief obtained is often erroneously attributed to the medication where other factors may be responsible.

Of the factors to be considered, the most important one is the psychologic effect of the new drug, especially if given by injection. Other factors are the relative amount of rest and relaxation that the patient is receiving during the treatment as compared to that before treatment; the general constitutional and mental state of the patient, which varies from time to time and which has an influence on the perception of pain; the care as to food, the digestive apparatus, and so on. One has only to look at the array of drugs and medicaments that were recommended in the past for this syndrome and highly praised by their proponents, but were discarded later as practically useless. Case 7 is one in which relief might be attributed to a material which has no therapeutic value, if no consideration is given to the other factors which may be responsible for the relief.

It is for these reasons that we report the apparently definite therapeutic effects of testosterone propionate in some cases of the anginal syndrome with considerable hesitancy and caution. We do not wish to be too optimistic from the results on the limited number of cases that we observed. Although our success has not been as frequent, nevertheless our findings appear to substantiate the claims of other observers, mentioned in the early part of this paper, of the beneficial effects of testosterone propionate in angina pectoris. The number of cases that showed a definite response is relatively smaller in our series. We believe that it is worthy of further trial in a greater number of cases.

There are two objections to the use of the product. One is the cost, which is very high, and the other is the necessity for its parenteral

use. These objections are partly overcome by the fact that effective results may be obtained by administering the product only twice weekly.

If further use of the product in the anginal syndrome proves it to be successful even in the proportion of cases we observed and if it can be produced in a form suitable for oral use and at a cheaper price, it may prove to be a very valuable adjunct in therapy of the most troublesome form of cardiovascular disease.

EXAMINATIONS IN OBSTETRICS AND GYNECOLOGY

Applications for the 1944 examinations of the American Board of Obstetrics and Gynecology are being received at the office of the secretary, Dr. Paul Titus, 1015 Highland Building, Pittsburgh, Pennsylvania. Booklets of information regarding Board requirements and examinations, together with application forms, will be sent upon request.

All applications for the year 1944 must be in the Secretary's Office not later than November 15, 1943, ninety days in advance of the Part I examination date.

Candidates are required to take both the Part I and Part II examinations. The Part I examination consists of the written paper and the submission of twenty-five case-history abstracts, and will be conducted on Saturday, February 12, 1944. This examination will be arranged so that the candidate may take it at or near his place of residence. Upon the successful completion of the Part I examination, candidates are eligible for the Part II examination, which consists of an examination in pathology and an oral examination. This is given at the annual meeting of the Board once each year, the time and place of which will be announced later.

The Office of the Surgeon General (U.S. Army) has issued instructions that men in service who are eligible for Board examinations be encouraged to apply and that they request orders to "detached duty" for the purpose of taking the examinations whenever possible.

The annual meeting of the American Board of Obstetrics and Gynecology was held at Pittsburgh from May 20 to May 25, at which time 108 candidates were certified.

A number of changes in Board regulations and requirements were put into effect. Several of these changes are designed to broaden the requirements for candidates in service. Examples are the allowance of a stipulated amount of credit toward special training requirements for men in service and assigned to general surgical positions, special training allowances on a preceptorship basis for men assigned to obstetric or gynecologic duties in military hospitals and working under the supervision of diplomates or recognized obstetrician-gynecologists, as well as credit toward the "time in practice" requirement of the Board to be allowed for time in military service.

The Board will no longer require a general rotating internship, but will now accept a one-year intern service, although the rotating internship is preferable. Such services must be in institutions approved by the Council on Medical Education and Hospitals of the A.M.A. Lists of such institutions are published regularly in the Educational Number of *J.A.M.A.*

The privilege of reopening applications by candidates who have been declared ineligible has been extended to two years from date of filing the application, instead of one year.

The Board has ruled temporarily to excuse men in military service from the submission of case records at the stipulated examination times, thereby permitting them to proceed without further delay with the Board examinations. This does not obligate the Board, however, to waive the case-record requirement for such candidates. Plans have been made to provide similarly for service men upon their eventual discharge from the armed forces and to permit the greater use of operations done while in residency or in civilian practice before the war.

Prospective applicants or candidates in military service are urged to obtain from the Office of the Secretary a copy of the "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards," which will be supplied upon request. This record was compiled by the Advisory Board for Medical Specialties and is approved by the offices of the Surgeons General. It will enable prospective applicants and candidates to keep an accurate record of work done while in military service and should be submitted with the candidate's application, so that the Credentials Committee may have this information available in reviewing the application.

Applications and bulletins of detailed information regarding the Board requirements will be sent upon request to the Secretary's Office, 1015 Highland Building, Pittsburgh, Pennsylvania.—*Paul Titus, Secretary*

INTRACRANIAL ARTERIOGRAPHY WITH RAPIDLY EXCRETED IODINE COMPOUND (DIODRAST)

J. Lawrence Pool, M.D., and Stewart Alexander, M.D., New York City

INTRACRANIAL arteriography, a useful diagnostic procedure, had fallen into disrepute until the present time because the dye formerly employed (thorium dioxide or thorotrast) proved to be radioactive. Thorium dioxide (thorotrast) is not to be confused with the *iodine* compound, *diodrast*, used by us and described in the present communication. While somewhat similar in name, the two substances have entirely different characteristics. Diodrast, commonly used for intravenous pyelography, is not radioactive and is entirely eliminated from the body within a few hours after intravenous or intra-arterial injection. Furthermore, in weak concentration it has not proved harmful to the blood vessels or to the organism as a whole, even when introduced directly into an internal carotid artery. We have used diodrast, with no ill effects, for purposes of intracranial arteriography in 9 cases. (A total of 30 injections of from 8 to 15 cc. apiece were made.) The procedure has obvious merit for the localization of intracranial aneurysms, angiomata, neoplasms, etc.

Diodrast is 3,5 diiodo-4-pyridone-N-acetic acid and diethanolamine. It contains 49.8 per cent iodine firmly bound as organic iodide, and is the same material that is commonly used for intravenous pyelography, in which its rapid elimination by the kidneys renders it effective as a diagnostic agent. We have used only the 35 per cent solution. In the small dosages administered (8 to 15 cc.), none of the systemic changes which have followed large intravenous injections[1,2] have been observed. There is an action of vasodilatation, which might suggest that headache would follow intracarotid injection, but this has occurred in only one of our 9 cases. There have been no significant alterations in pulse rate, blood pressure, or respiratory rhythm either during or after the injections. In the use of the 35 per cent solution, there is a negligible chance of vascular thrombosis as attested to by the infrequency of this complication following intravenous pyelography. If the stronger 70 per cent solution is used, this risk is naturally enhanced and has been known to occur, Robb and Steinberg[1] having noted 33 cases of thrombophlebitis following the intravenous injection of the 70 per cent diodrast in their first 238 cases. The 35 per cent concentration of diodrast, however, produces no perceptible injury to the blood vessels of man[3,4] or animal.[4] For this reason several injections with x-ray exposures may be made in one patient at a single sitting with no great risk or difficulty.

Priority for the intracranial use of diodrast justly belongs to Dr. Sidney Gross,[6] who recently reported a series of 10 cases in which the dye had been used. However, he injected the stronger—70 per cent—solution and noted alterations in pulse rate, subjective sensations of discomfort, and occasional convulsive manifestations in some of his patients. No such reactions were observed in our series, wherein the weaker 35 per cent concentration was employed. Reports from another source in which the 70 per cent dye was used indicate that disastrous sequelae can occur, one patient having suffered a long-standing hemiplegia and coma following the procedure, and another having shown complete thrombosis of the carotid artery when it was reexposed some forty-eight hours after the first injection of the more concentrated solution.

It may be of interest to state that our work with the 35 per cent solution was begun in July, 1939, at Bellevue Hospital, without the knowledge that others were using this substance for the same purpose. The application of the 35 per cent solution was instigated by one of us (S. A.), who had previously had considerable experience with diodrast in outlining the great vessels of the heart and lungs.[7]

A total of 9 patients comprises our series. In all of them it was possible to obtain visualization of intracranial blood vessels on the injected side of the head, although it must be acknowledged that in some of the earlier instances the visualization was not wholly satisfactory. The greatest stumbling block proved to be difficulty in coordinating the x-ray exposure with the injection of the dye. This has been largely overcome with greater experience. The cases studied were those in which a unilateral intracranial lesion was suspected. So far we have not conclusively demonstrated any pathology by this procedure.

Technic

All cases were injected by way of the internal carotid artery under local anesthesia. Preliminary medication consisted of morphine sulfate, grain $1/6$ or $1/4$, supplemented by scopolamine, grain $1/150$. After preliminary infiltration of the skin with 1 per cent procain hydrochloride, suitable drapes were sutured to the skin so that the

From the Neurological Service, Bellevue Hospital, New York City.

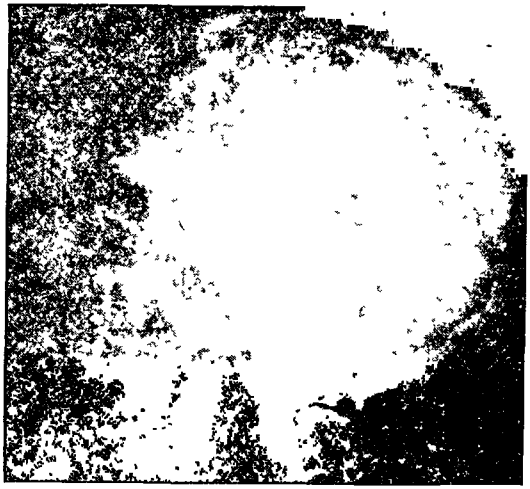

FIG. 1. Lateral view of skull showing outline of vessels of left side of brain during injection of 35 per cent diodrast into left internal carotid artery.

head could later be manipulated without endangering the sterility of the operative field. A 3-cm. oblique incision was made parallel to the sternocleidomastoid muscle, extending upward from the level of the thyroid cartilage. The incision was carried through the platysma by sharp dissection and continued by blunt dissection with curved scissors until the external carotid artery was exposed. A coarse silk ligature was then passed beneath this artery with an aneurysm needle so that it could be gently retracted, thus exposing the internal carotid.

A ligature was passed in similar fashion around the internal carotid artery, care being taken not to include or traumatize the nerves within the carotid sheath. Subcutaneous and cutaneous sutures were placed but not tied. The patient was then transferred to the x-ray room. The entire procedure was carried out on a stretcher.

When the subject was in position beneath the x-ray apparatus, the internal carotid artery was exposed by suitable retractors, and a curved No. 18 needle was inserted into its lumen. The needle was next connected to a stopcock and syringe filled with 15 cc. of diodrast. A section of rubber tubing about 4 cm. in length intervened between needle and stopcock, so that the operator's hands would not be in the line of x-ray fire. With everything in readiness, 5 to 8 cc. of dye were rapidly injected into the vessel, whereupon the x-ray exposure was begun, and the injection continued until the exposure was completed. The total dye injected amounted to from 10 to 15 cc. The x-ray exposure lasted one second, at 200 millivolts. A Bucky diaphragm was always used. From two to four injections were made on each patient at intervals of from two to five minutes. It was possible to take not only lateral views but also anteroposterior views. A sample film is shown in Fig. 1. On completion of the procedure the needle was withdrawn, the wound packed with gauze, and gentle pressure exerted for from two to five minutes This always served to control extravasation of blood from the site of puncture. The subcutaneous and cutaneous sutures previously placed were now tied and the patient returned to his bed. No drains were necessary.

In conclusion it seems worth repeating that diodrast in 35 per cent concentration is a suitable radiopaque medium for injection into the internal carotid artery, and must not be confused with thorotrast, which is no longer considered a safe dye for the purpose of angiography, intracranial, or other uses.

Summary

Intracranial arteriography can be safely carried out with 35 per cent diodrast. Stronger solutions of this dye are apparently not safe; 8 to 15 cc. of the material may be injected under local anesthesia, as many as four times at one sitting, into an internal carotid artery without ill effects.

PARMLY FOUNDATION FOR RESEARCH

The Parmly Foundation has been established at the Illinois Institute of Technology to carry on research in hearing. The foundation, which was created through a trust fund of $300,000 set aside by the late Samuel P. Parmly, Jr., a Chicago business man, will concentrate its work on the physics of hearing and plans to cooperate with the medical profession on other aspects of the problem. This is in accordance with the plan of Mr. Parmly, who also stipulated that the research must be done at an institution of learning.—*Journal of the Association of Medical Colleges*

Clinicopathologic Conferences

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

Conducted by: Herman O. Mosenthal, M.D., and Maurice N. Richter, M.D.

Date: December 15, 1942

History

Case J70719

DR. WOODBURY PERKINS: A 70-year-old Greek man was admitted on September 29, 1942. His chief complaints were of weakness for two months and poor appetite for one month, during which time he had lost 12 pounds. For six weeks he had had 3 or 4 small stools a day and complained of a feeling of inadequacy in emptying the bowels. The stools at no time appeared to contain blood. There was no jaundice, fever, chills, vomiting, or pain. There was constant nausea, and he suffered from occasional night sweats. His past and personal histories were negative.

Physical examination revealed a moderately obese, chronically ill, tired, 70-year-old white man in no acute distress. Temperature, pulse, and respirations were normal. Blood pressure was 110/70 mm. of mercury. There was no jaundice. The pupils were slightly irregular and unequal, but they reacted to light and accommodation. The trachea deviated slightly to the right. The lungs were clear. The heart was not enlarged to percussion, and the sounds were of good quality, with a blowing systolic murmur at the apex. There was regular sinus rhythm. The liver edge, palpated two fingerbreadths below the costal margin, was smooth and slightly tender. The spleen was not felt. Rectal examination revealed a large, smooth, soft prostate.

Laboratory Data.—Blood count: hemoglobin, 15.7 Gm.; red blood cells, 4.96 million; white blood cells, 6,950; differential count—59 per cent polymorphonuclears, 28 per cent lymphocytes, 10 per cent monocytes. Urinalysis: faint trace of albumin, specific gravity 1.016, no red blood cells or casts. The blood Wassermann was negative. Blood chemistry: nonprotein nitrogen, 22.5 mg. per cent; urea nitrogen, 10.0 mg. per cent; cholesterol, 210 mg. per cent; esters, 130 mg. per cent; total serum proteins, 7.6 Gm. per cent; albumin/globulin ratio, 4.8/2.8; icterus index, 10.7 units; bromsulfalein, 40 per cent retention in thirty minutes, 32 per cent retention in sixty minutes

Clinical Course.—The patient was afebrile except for three occasions when his temperature rose to 101–102 F. for one day. He complained constantly of weakness, anorexia, nausea, and insomnia. The gastrointestinal series revealed the stomach to have "funnel-shaped scirrhous-like appearance of the antrum," and the colon was found to be "narrow and tubular throughout, with diminished haustrations." The barium colon enema showed "isolated diverticuli in the sigmoid." An x-ray of the chest showed the heart to be slightly enlarged to the left, and there was evidence of pleuritic thickening and adhesions at both bases with obscuration of the costophrenic sinuses.

On October 9 the patient became jaundiced. At this time the icterus index was 23.0 units, urobilin 171.7 mg., and the cephalin flocculation test was 4 plus.

During his second week in the hospital the patient was subject to insomnia, dyspnea, moderate pain in the right upper quadrant, and watery diarrhea. The stools were negative to Guaiac. His blood pressure was 110/94 mm. of mercury and the pulse 104, with occasional premature ventricular contractions. His heart had shifted to the left so that the apex beat was visible 12 cm. to the left of the sternum in the fourth intercostal space. He had moist rales at the base of both lungs. He was observed to sleep propped up against the wall with his feet hanging over the edge of the bed. In such a position, his legs became blue and edematous. An electrocardiogram showed premature contractions and left axis deviation. He was digitalized but without any perceptible improvement in his condition.

On October 14, an x-ray of the chest showed the heart to be enlarged to the left, a high right diaphragm, and obscuration of the costophrenic angles. Concerning the increased pleural thickening, the radiologist noted "probable abdominal pathology to be considered the most likely causative factor." Repeated determinations of serum proteins were normal.

Thus, as the patient went into his third and final week in the hospital, he presented the picture of a chronically ill, 70-year-old man, lying uncomfortably in bed, afebrile, dyspneic,

listless, depressed, and without appetite. He was icteric, had a symmetrically enlarged, smooth, tender liver, and had a heart enlarged to the left with the classical signs of cardiac failure which had not responded to adequate digitalis therapy. He died quietly on October 17, the evening of his nineteenth day in the hospital.

Clinical Diagnosis

Laennec's cirrhosis of the liver.
Arteriosclerotic heart disease.
Myocardial fibrosis.
Enlarged heart.
Cardiac failure.

DR. JEROME A. MARKS: Was any ascites observed?

DR. PERKINS: At one point it was believed to be present, but later the signs of fluid in the peritoneal cavity disappeared.

DR. MARKS: Was a blood sugar done?

DR. PERKINS: A blood sugar was done and was found to be within normal range.

Discussion

DR. MARKS: This case presents the interesting problem of diagnosis when meager symptoms referable to the digestive system occur in an older person, for these symptoms (anorexia, nausea, tendency to diarrhea, and weight loss) are so unspecific that they might be called by the generic term "dyspepsia."

Dyspepsia, it is important to remember, may result from disease in any system of the body in addition to the gastrointestinal tract proper. The most important of these are indicated in Table 1, and in any case of dyspepsia they must be given careful consideration before attention is finally turned to the abdominal organs.

TABLE 1

1.	Cardiovascular system
2.	Pulmonary system
3.	Genitourinary tract
4.	Metabolic disease
5.	Blood dyscrasias
6.	Lues

In this case, the *cardiovascular* system does not appear to be involved. There is no antecedent history of cardiac disease and, except for a systolic murmur, no signs of cardiac involvement. The heart size, sounds, and rhythm are all normal, as well as the blood pressure, the vasculature, and the electrocardiogram.

The *pulmonary* system may be excluded also, for though there are minor diaphragmatic and pleural changes, these are most probably referable to abdominal pathology.

The normal blood chemistry and urine examinations rule out *genitourinary* tract disease (particularly uremia) as causing this patient's symptoms, and there is no evidence that *metabolic disease* exists.

Finally, the normal blood count rules out *blood dyscrasias* (notably leukemia), and the negative Wassermann test excludes *syphilis*.

Having thus disposed of the main extra-abdominal causes of "dyspepsia," our attention is focused finally on the gastrointestinal tract, the accessory organs of digestion (liver, pancreas), the peritoneum, omentum, and retroperitoneal structures.

Let us briefly recapitulate the essential history and findings of this case—recent weight loss, anorexia, nausea, night sweats, and watery diarrhea associated with a tender mass in the right upper quadrant, together with essentially normal laboratory studies except those that point to liver involvement, such as progressive increase in the icterus index and moderate bromsulfalein retention.

Our attention is therefore drawn to the liver as the cause of this patient's symptoms, and a resolution of the nature of his hepatomegaly will probably explain the entire picture.

In Table 2, I have listed, in roughly ascending order of occurrence, the commoner causes of hepatomegaly.

TABLE 2

1.	Lues
2.	Hydatid disease
3.	Abscess
	(*a*) Amebic
	(*b*) Multiple
4.	Subphrenic abscess
5.	Hepatitis
6.	Chronic passive congestion
7.	Cirrhosis
8.	Carcinoma
	(*a*) Primary
	(*b*) Secondary

Analyzing these possibilities, we can dispose of lues at once because of the negative Wassermann test. Hydatid disease of the liver, though rare, deserves consideration because of the patient's nationality (Greek) and because of the pleural involvement as seen in the x-ray of the chest. Although there is nothing else in the history to suggest this diagnosis, I think a complement-fixation test would have been indicated if the patient had lived.

Abscess of the liver might be either of the solitary amebic type or multiple. The remote possibility of the former is suggested by the recent watery diarrhea, but except for this there is nothing in either the history or the barium enema to indicate amebiasis. Pyemic (multiple) abscess may be ruled out by the afebrile course, lack of history, and absence of leukocytosis.

These will also serve to exclude subphrenic abscess.

A much commoner cause for hepatomegaly and jaundice would be hepatitis, but this is seldom afebrile and less often fatal, unless acute yellow atrophy sets in, which obviously did not occur here. In addition, no causative factor such as the use of drugs or occupational contacts was demonstrated.

During the patient's stay in the hospital, he developed signs of cardiac failure (basal rales, dyspnea, and progressive enlargement of the heart). However, that chronic passive congestion was not the cause of his hepatomegaly is indicated by the fact that it was present on admission when the later signs of decompensation were still entirely absent.

Cirrhosis of the liver is an exceedingly likely diagnosis. This disease is common in Mediterranean people, and furthermore, the diagnosis is favored by the positive cephalin flocculation test. However, three things stand against it: first, the late onset (age 70) and the absence of any suggestive history of alcoholic excess or previous gastrointestinal symptoms; second, the absence of splenomegaly, and third (and most important), the persistently normal serum proteins and albumin/globulin ratio.

We finally come to consider carcinomas, both primary and metastatic, as the disease process from which this patient died. It appears to me that the sudden onset of anorexia, nausea, weight loss, and rapidly progressive deterioration in a 70-year-old man inescapably point to this diagnosis. Here the problem becomes one of determining (if possible) the exact nature of the lesion.

Primary carcinoma of the liver, though relatively rare ($^1/_{10}$ of 1 per cent of all autopsies) must be given careful thought. This diagnosis is rendered more probable by the rapidity of the entire process (two and one-half months to death), the smooth, enlarged liver, and the absence of splenomegaly. In my experience, carcinoma of the liver occurs in somewhat younger individuals (and averages, according to Sir Humphry Rolleston, about 49 years), though this in no way excludes the diagnosis. However, the existence of primary carcinoma is weakened on statistical grounds since secondary carcinoma occurs 20 to 40 times more commonly (Rolleston) and thus deserves our immediate consideration.

In diagnosing metastatic carcinoma, the demonstration of the primary focus is obviously most important, and to this end the gastrointestinal series will be of greatest value. The roentgenologist describes a scirrhous process in the antrum. I cannot agree to this because the shape of the stomach appears to be due to extrinsic pressure both from above and below, and no evidence of gastric neoplasm is noted. The colon too, while showing a colitis, fails to reveal any sign of neoplasm.

No primary focus having been found, we must consider the possibility that the lesion is in an organ not easily subject to visualization by the x-ray—i.e., the pancreas. Carcinoma of this organ is fairly common (six times more so than primary liver carcinoma), metastasizes rapidly, and presents a clinical picture quite similar to that given in this case. Unfortunately, there are no pancreatic function tests to support or disprove this diagnosis.

The remote possibility that the tumor mass we are feeling is not liver at all but omentum, kidney, etc., must be considered. This, however, is unlikely because of the obvious involvement of the liver as shown by the liver function tests.

In conclusion, therefore, I feel that we are dealing with a carcinoma whose primary source has not been shown to be in the gastrointestinal tract proper and which therefore may be in the liver or, what is six times more probable, in the pancreas, with secondary metastases to the liver.

Dr. Marks' Diagnosis

Carcinoma of liver, secondary to pancreatic carcinoma.

DR. HERMAN O. MOSENTHAL: One thing that comes to my mind is that the patient might have had cirrhosis of the liver which may have caused some of the gastric symptoms.

Pathology

DR. MAURICE N. RICHTER: The main interest is in the liver. This is the seat of cirrhosis and has in addition a large tumor mass in the right lobe. The center of the tumor is necrotic. It invades the diaphragm, which is adherent to the upper surface. The tumor extends posteriorly and invades the hepatic veins and inferior vena cava, the lumen of which is reduced to half its normal size. Below the point of invasion is a mural thrombus in the inferior vena cava, extending down to include the common iliac veins

A small amount of fluid was present in the peritoneal cavity, and fluid was present also in the right pleural cavity. There was moderate emphysema, and a number of other incidental findings that do not bear directly on the diagnostic problem, but are listed below in the anatomic diagnosis.

Microscopically, the tumor is a primary carcinoma of the liver, arising from liver cells. The resemblance between tumor cells and liver cells is striking, and is enhanced by the finding of

hyaline degeneration of the cytoplasm in both types of cell. This type of degeneration is not uncommon in cirrhosis.

The only metastases found were in the lymph nodes along the inferior vena cava and upper abdominal groups. The same hyaline degeneration found in the liver cells and in the primary tumor were found in the metastases.

The association of cirrhosis with carcinoma is well known and is of high but variable incidence in the reports of different laboratories.

Anatomic Diagnosis

CARCINOMA OF LIVER; ORIGIN, LIVER CELLS.
Cirrhosis of liver, portals.
Secondary carcinoma of diaphragm, inferior vena cava, and lymph nodes (pancreaticolienal and upper gastric).
Thrombosis of inferior vena cava and tributary veins.
Sclerosis of coronary arteries.
Fibrosis of myocardium.
Hydrothorax, right.
Ascites.
Chronic passive congestion of liver and spleen.
Edema of lower extremities.
Emphysema of lungs.
Trichinosis.
Indirect inguinal hernia, right, with incarceration of ascending colon.

DR. MOSENTHAL: You did find fibrosis in the myocardium?

DR. RICHTER: Yes. Death was due apparently to cardiac failure.

DURATION OF PREGNANCY

Recent regulation changes by which the classification of registrants is to be established under the Selective Service System provide for a distinction between (1) men with child (or children) with whom they maintain a family relationship in their homes, provided such status (child) was acquired prior to December 8, 1941, and (2) men with wives only or with child (or children) acquired after December 8, 1941. As a result of these provisions, it will become necessary for local Selective Service boards to determine beyond reasonable doubt in certain borderline instances whether a child was conceived before or after December 8, 1941, in order to classify the registrant correctly.

Many reports have a bearing on this problem. Wahl studied a series of 9,000 women to determine the length of pregnancy. He found that the average duration of gestation was 285 days, which is contrary to commonly quoted figures of 280 days. As pointed out by Schwarz, pregnancy actually begins the moment the female egg cell becomes fertilized and ends with the birth of the child. The time estimated as the length of pregnancy is difficult to determine on account of several variable factors: (1) the question of the time of ovulation, (2) the time of migration, (3) the lifetime of the egg and the spermatozoa, (4) the time of impregnation, and (5) the time of implantation of the ovum.

The Hotellings, who analyzed over 2,000 obstetric cases at the Sanford University Clinic, came to the following conclusions: "The conclusion of the earlier writers that 280 days is the average duration of normal pregnancy—that is, when the very short and very long durations are excluded—is confirmed by our study. However, the standard deviation from this average, which other students have estimated to be from 8 to 10 days, we find to be 11 days.

"If early births are included, the mean duration is shorter and the standard deviation greater. The mean duration from the date of coitus to birth is 271 days, the standard deviation being scarcely any less than when duration is counted from the beginning date of the last menstruation. The standard deviation also seems to be no less when duration is counted from the last day of the last menstruation, as in England and France. Accordingly, there is no perceptible gain in accuracy by reckoning even from a single coitus of known date, unless, of course, the menstruation date is unknown."

The longest possible period of gestation has not been legally defined in this country. French law recognizes the legitimacy of a child born 180 days after marriage and 300 days after the death of the husband; the German law, 181 and 302 days, respectively. In England in 1921 the legitimacy of a child born 331 days after the husband went to war was allowed. In the United States each case is decided on its own merits, since there is no law in this country or in England which defines the duration of gestation.

The problem is further complicated by the fact that there are no accurate criteria for ascertaining the degree of hypermaturity of newborn infants; even fully formed teeth are sometimes found in those born at term. It can only be said that the weight of the newborn child when evaluated against the size of the parents and parity of the mother can be highly suggestive.

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the September 1 issue and will concern "Carbon Monoxide Poisoning."

The Doctor's Bag

DR. C. H. WHEELER: The topic for this morning is "The Doctor's Bag," a subject which I think will be self-explanatory, so I will ask Dr. Gold to start right off.

DR. HARRY GOLD: I thought it might be well to look into a few doctors' bags and see what there is in them, as a basis for the discussion this morning.

We examined the bags of 7 doctors, most of whom practice here in the center of New York. Here is what they contained in the way of medicines:

Dr. A.

Morphine sulfate	Hypodermic tablets
Codeine sulfate	Hypodermic tablets
Seconal	Capsules
Epinephrine	Ampules
Mercupurin	Ampules
Pituitrin	Ampules
Pitressin	Ampules
Amyl nitrite	Pearls
Ergone	Ampules
Coramine	Ampules
Camphor in oil	Ampules
Calglucon	Ampules
Trasentin	Ampules

Dr. B.

Morphine and atropine	Tablets
Pantopon	Tablets
Hyoscine HBr	Tablets
Nembutal	Capsules
Epinephrine	Ampules
Adrenalin in oil	Ampules
Coramine	Ampule
Digifolin	Ampules
Esidrone	Ampules
Nitroglycerine	Tablets
Prostigmine	Ampules
Gynergen	Ampules

Dr. C.

Morphine	Hypodermic tablets
Nembutal	Capsules
Amytal	Capsules
Coramine	Ampules
Digifortis	Ampules
Adrenalin	Ampules
Esidrone	Ampules
Salyrgan-theophylline	Ampules
Mercupurin	Ampules
Pituitrin	Ampules

Dr. D.

Morphine and atropine	Ampules
Dilaudid	Hypodermic tablets
Codeine	Hypodermic tablets
Hyoscine HBr	Hypodermic tablets
Nembutal	Capsules
Amytal	Tablets, gr. 1½
Amytal	Tablets, gr. ¾
Sodium amytal	Capsules, gr. 1½
Sodium amytal	Capsules, gr. 3
Seconal	Capsules
Atropine sulfate	Hypodermic tablets
Adrenalin	Ampules
Gynergen	Ampules
Ephedrine and amytal	Capsules
Coramine	Ampules
Caffeine-sodium benzoate	Ampules
Betaxin	Ampules
Thiamine and amytal	Ampules
Amyl nitrite	Pearls
Allonal	Tablet
Esidrone	Ampules

Dr. E.

Morphine sulfate	Vials 3%
Pentobarbital	Capsules
Epinephrine	Ampules
Mercupurin	Ampules
Digitaline Nativelle	Tablets

Dr. F.

Morphine sulfate	Hypodermic tablets
Adrenalin	Ampules
Alcohol	
Tincture merthiolate	

Dr. G.

Morphine and atropine	Hypodermic tablets
Morphine sulfate	Hypodermic tablets
Codeine sulfate	Hypodermic tablets
K-Y jelly	
Adrenalin	Ampules
Metaphen	
Alcohol	

The contents vary a good deal. One has only 4 items and another as many as 21.

Every one of these bags seems to be very well supplied with medicines to help the patient forget his troubles. They all have some narcotic, like morphine or codeine, or both, or dilaudid. Most of them have some form of sedative, and every bag has a dose of adrenalin.

If one examines the lists carefully, one will see

that only 3 of the 7 doctors are prepared to meet the emergency of an attack of acute heart failure with any of the drugs in their bags. If Dr. F. were called in the middle of the night to see a patient with acute pulmonary edema or acute left heart failure, he would be in a bad way—that is, from the standpoint of the extent to which a medicine can help. Dr. B. has a digitalis preparation, but only one ampule, a cat unit of digifolin for hypodermic injection. That would not help him very much. Dr. D.'s bag has 21 items. It is the most heavily stocked of the bags we examined, but, even so, he also is unprepared to treat an attack of acute heart failure or pulmonary edema, an attack of diabetic coma, or of insulin shock, a convulsion, or a case of acute drug poisoning. Let us suppose that the patient has just swallowed a dose of bichloride of mercury, and every minute counts. Is there anything there to help empty the stomach?

One cannot be dogmatic about what the contents of the doctor's bag should be. It depends on so many factors. A consultant should need very little in his bag, although, if one judges from the foregoing lists, the consultant might do well to carry more. The person who practices in the rural district, in which it is very difficult to find a pharmacy open at night or even in the daytime, needs a miniature pharmacy in his bag. That might not apply to certain sections of Manhattan.

Just before the session this morning I had occasion to see another bag, belonging to one who has put a good deal of thought and planning into it. These were the chief items: tablets of morphine, atropine, codeine, nitroglycerine, quinidine, digitalis leaf, phenobarbital, nembutal, aspirin, veracolate (a laxative), and sulfadiazine. There were urotropin tablets as a source of flame for sterilizing the hypodermic needle and syringe. There were ampules of sodium phenobarbital, adrenalin, adrenalin in oil, caffeine sodium benzoate, coramine, procaine solution, sterile distilled water, morphine solution, aminophylline, and mercupurin. This is by long odds the best equipped bag of the lot, yet an attack of acute heart failure in which a half hour or an hour might be decisive would still prove embarrassing. It contains no parenteral digitalis material. The patient in acute cardiac failure may be in coma or may be vomiting so that oral digitalis is out of the question. Nor does this bag provide a ready means for emptying the stomach if the patient has accidentally swallowed a poison in which minutes count. It is also unprepared for meeting the case of diabetic coma or insulin shock.

One might argue that the fact that doctors do not carry these items indicates they they probably do not encounter these conditions in general practice often enough or that they have means of securing them with dispatch when the emergency arises. Perhaps, however, we ought to consider the subject of the doctor's bag more broadly, from the standpoint of being prepared, in so far as it is possible, to meet practically all emergency situations in which a drug might help.

I have drawn up a list, which I am quite sure is not complete, but which I think comes fairly close to meeting every emergency condition in which a drug may be very helpful or even decisive. The order in which I list them is not the order of their importance.

1. Hypodermic tablets of apomorphine hydrochloride, $^1/_{10}$ grain. With these the stomach may be emptied very quickly and more certainly than by almost any other means. Mechanical stimulation of the pharynx is sometimes effective, but a great many patients will merely gag and not vomit.

2. Syrup of ipecac is a very useful agent to have in a bag. It can serve two major functions and perhaps some minor ones. It is about as effective an agent as we have to relieve a paroxysm of auricular tachycardia, and if there should be no apomorphine available, it could very well take its place as an emetic in a dose of 3 or 4 teaspoonfuls. Smaller doses would not insure rapid vomiting.

3. Morphine sulfate. Almost everyone has that. Hypodermic tablets of $^1/_4$ grain or a sterile solution of morphine in a vial are the most suitable forms. Tablets of codeine are useful, although not essential.

4. Digitaline Nativelle, 0.2 mg. tablets. If the patient is in advanced heart failure, give him 6 of these at one time, providing he has had little or no digitalis recently. It will digitalize safely in a few hours.

5. Ouabain, 2 cc. ampules containing 0.5 mg. of ouabain each, ought to be in every bag for the emergency in which hours may be decisive or the patient is vomiting and oral digitalization is not feasible.

6. Tablets of phenobarbital, $^1/_2$ grain, as a sedative.

7. Capsules of pentobarbital sodium, $1^1/_2$ grains. If one gives a fairly large dose of pentobarbital sodium, 3 grains, one is fairly sure that the patient will fall asleep, with little likelihood of marked depression the following day.

8. Phenobarbital sodium. It comes in ampules in the form of a powder. The 130 mg. ampule is the most useful size. It is dissolved in water and injected subcutaneously.

9. Ethyl chloride in a spray tube. This may be used as a volatile anesthetic to control a convulsion. It may also be used as a local anesthetic to incise a boil. It is a great help to have ethyl chloride in the bag for the case in which the

patient may have had the boil several days but calls you at 2:00 A.M. because the pain has increased beyond the limits of endurance.

10. An ampule of 50 per cent glucose, 50 cc., would help to meet the emergency of an insulin shock.

11. Ampules of mecholyl, 25 mg., for the attack of paroxysmal tachycardia. Give this dose subcutaneously when other less risky measures have failed. It rarely fails to terminate an attack promptly.

12. Hypodermic tablets of atropine sulfate, 1/150 grain, are needed in connection with the mecholyl. One should avoid injecting a dose of mecholyl unless a dose of atropine is at hand in another syringe.

13. Tablets of quinidine sulfate, 5 grains. If a patient develops an attack of auricular fibrillation giving rise to a severe reaction with cardiac pain and cold and clammy skin, he presents an emergency case. A dose of 15 grains every two hours will terminate the attack with dramatic relief.

14. Ampules of quinine dihydrochloride. In case the disorder of rhythm is more serious, such as ventricular tachycardia following an acute coronary thrombosis and the ventricular rate is 180 a minute, oral medication may not suffice. Quinidine is not available in solution for intravenous injection. The soluble form of quinidine does not keep. We use quinine dihydrochloride, a 20 cc. ampule, which contains 32 mg. of quinine dihydrochloride per cc.

15. Ampules of mercupurin, 2 cc., or some other organic mercurial diuretic. Every bag ought to have it to meet the condition of cardiac asthma or acute pulmonary edema. It does not act very quickly but after one has applied other measures one obtains more rapid recovery and insures against a recurrence by a prompt injection of a dose of mercupurin.

16. Ampules of theophylline ethylenediamine, about 3½ grains in 10 cc. It is helpful in the case of status asthmaticus. In the typical case presenting an emergency, the trouble starts early in the evening. The patient has been taking epinephrine injections, but now he does not seem to be responding, and two or three hours later the sense of suffocation becomes extreme. An intravenous injection of about 3½ grains sometimes provides relief. There are other emergency uses for this ampule.

17. Ampules of epinephrine, 1:1,000 solution, 1 cc.

18. Ampules of ergotamine tartrate, 1:1,000 solution, 0.5 mg. per cc. This helps to meet the occasional attack of severe migraine. It may be given intramuscularly but is more effective if given intravenously.

19. Ampules of solution of posterior pituitary, 1 cc. If one has any amount of obstetric practice, he might want to have that readily available.

20. Vial of insulin. This is useful for the emergency of acute diabetic coma.

21. Hypodermic tablets of nitroglycerine, 1/150 grain. Ordinary tablet triturates are often so hard that they remain too long under the tongue without dissolving, whereas the hypodermic tablet disintegrates almost immediately. It relieves the attack of coronary insufficiency.

22. Pearl of amyl nitrite. This might be used for some of the more severe attacks of coronary insufficiency, since its action is almost instantaneous.

23. Alcohol, approximately 70 per cent solution.

24. Sulfanilamide powder. Sterile packets are available to dust into a wound. Of course, it must be used with caution.

25. Tablets of sulfadiazine, 7½ grains.

26. Tablets of aspirin, 5 grains.

27. Solution of ephedrine sulfate, 1 per cent, for relieving severe head symptoms resulting from acute sinusitis or nasal congestion. Any of the substitutes belonging to this class of preparation will do.

28. Solution of picrotoxin, 0.3 per cent. A 20 cc. vial is available. It contains 3 mg. per cc. If one comes upon a case of barbiturate poisoning—an attempt at suicide with one of the hypnotics of the barbiturate group, with the respiration 3 or 4 a minute and signs of collapse—the injection of 10 mg. intravenously every twenty minutes until signs of hyperexcitability occur may add weight to the possibility of recovery.

29. Solution of pontocaine, 1 per cent. This is a useful local anesthetic for topical application. One or two drops into the conjunctiva relieves a painful conjunctivitis and makes it easier to remove a foreign body from the eye.

30. Ampules of calcium gluconate. A 10 cc. ampule of a 10 per cent solution of calcium gluconate is available. I am not sure whether that ought to be carried about. But there are few agents that will act as effectively against an attack of lead colic. If one is engaged in practice in which lead colic is likely to be encountered, perhaps that person should have it.

In listing the chemical agents that should be found in the doctor's bag I have mentioned a use or two to which they might be put. These are merely suggestive. There are other conditions in which some of them may prove helpful in tiding over an emergency.

I want to mention just one mechanical device which ought to be carried, I think, in every bag because the cases for which it is useful are com-

that only 3 of the 7 doctors are prepared to meet the emergency of an attack of acute heart failure with any of the drugs in their bags. If Dr. F. were called in the middle of the night to see a patient with acute pulmonary edema or acute left heart failure, he would be in a bad way—that is, from the standpoint of the extent to which a medicine can help. Dr. B. has a digitalis preparation, but only one ampule, a cat unit of digifolin for hypodermic injection. That would not help him very much. Dr. D.'s bag has 21 items. It is the most heavily stocked of the bags we examined, but, even so, he also is unprepared to treat an attack of acute heart failure or pulmonary edema, an attack of diabetic coma, or of insulin shock, a convulsion, or a case of acute drug poisoning. Let us suppose that the patient has just swallowed a dose of bichloride of mercury, and every minute counts. Is there anything there to help empty the stomach?

One cannot be dogmatic about what the contents of the doctor's bag should be. It depends on so many factors. A consultant should need very little in his bag, although, if one judges from the foregoing lists, the consultant might do well to carry more. The person who practices in the rural district, in which it is very difficult to find a pharmacy open at night or even in the daytime, needs a miniature pharmacy in his bag. That might not apply to certain sections of Manhattan.

Just before the session this morning I had occasion to see another bag, belonging to one who has put a good deal of thought and planning into it. These were the chief items: tablets of morphine, atropine, codeine, nitroglycerine, quinidine, digitalis leaf, phenobarbital, nembutal, aspirin, veracolate (a laxative), and sulfadiazine. There were urotropin tablets as a source of flame for sterilizing the hypodermic needle and syringe. There were ampules of sodium phenobarbital, adrenalin, adrenalin in oil, caffeine sodium benzoate, coramine, procaine solution, sterile distilled water, morphine solution, aminophylline, and mercupurin. This is by long odds the best equipped bag of the lot, yet an attack of acute heart failure in which a half hour or an hour might be decisive would still prove embarrassing. It contains no parenteral digitalis material. The patient in acute cardiac failure may be in coma or may be vomiting so that oral digitalis is out of the question. Nor does this bag provide a ready means for emptying the stomach if the patient has accidentally swallowed a poison in which minutes count. It is also unprepared for meeting the case of diabetic coma or insulin shock.

One might argue that the fact that doctors do not carry these items indicates they they probably do not encounter these conditions in general practice often enough or that they have means of securing them with dispatch when the emergency arises. Perhaps, however, we ought to consider the subject of the doctor's bag more broadly, from the standpoint of being prepared, in so far as it is possible, to meet practically all emergency situations in which a drug might help.

I have drawn up a list, which I am quite sure is not complete, but which I think comes fairly close to meeting every emergency condition in which a drug may be very helpful or even decisive. The order in which I list them is not the order of their importance.

1. Hypodermic tablets of apomorphine hydrochloride, $^1/_{10}$ grain. With these the stomach may be emptied very quickly and more certainly than by almost any other means. Mechanical stimulation of the pharynx is sometimes effective, but a great many patients will merely gag and not vomit.

2. Syrup of ipecac is a very useful agent to have in a bag. It can serve two major functions and perhaps some minor ones. It is about as effective an agent as we have to relieve a paroxysm of auricular tachycardia, and if there should be no apomorphine available, it could very well take its place as an emetic in a dose of 3 or 4 teaspoonfuls. Smaller doses would not insure rapid vomiting.

3. Morphine sulfate. Almost everyone has that. Hypodermic tablets of $^1/_4$ grain or a sterile solution of morphine in a vial are the most suitable forms. Tablets of codeine are useful, although not essential.

4. Digitaline Nativelle, 0.2 mg. tablets. If the patient is in advanced heart failure, give him 6 of these at one time, providing he has had little or no digitalis recently. It will digitalize safely in a few hours.

5. Ouabain, 2 cc. ampules containing 0.5 mg. of ouabain each, ought to be in every bag for the emergency in which hours may be decisive or the patient is vomiting and oral digitalization is not feasible.

6. Tablets of phenobarbital, $^1/_2$ grain, as a sedative.

7. Capsules of pentobarbital sodium, $1^1/_2$ grains. If one gives a fairly large dose of pentobarbital sodium, 3 grains, one is fairly sure that the patient will fall asleep, with little likelihood of marked depression the following day.

8. Phenobarbital sodium. It comes in ampules in the form of a powder. The 130 mg. ampule is the most useful size. It is dissolved in water and injected subcutaneously.

9. Ethyl chloride in a spray tube. This may be used as a volatile anesthetic to control a convulsion. It may also be used as a local anesthetic to incise a boil. It is a great help to have ethyl chloride in the bag for the case in which the

mon, and often critical—namely, four pieces of rubber tubing which can be used as tourniquets for the case of acute pulmonary edema due to left heart failure. The application of these tourniquets to obstruct the return flow of blood to the arms and legs is sometimes a decisive measure in a desperate case.

DR. WHEELER: Dr. Guion, will you continue please?

DR. CONNIE M. GUION: Dr. Gold has covered the entire list of drugs needed in the doctor's bag and the indications for their use. I shall, therefore, lay more stress on the mechanical outfit in my bag. It includes this stethoscope with both a bell and a Bowles chest piece. This latter is very convenient for the examination of the lungs when the patient is supine and can be moved only with difficulty.

There is the sphygmomanometer, a light with an auroscope and ophthalmoscope, and two thermometers in glass containers filled with 75 per cent alcohol to keep them sterile. It is well to carry two thermometers in case you see two patients in one house or wish to leave one with a patient.

There are two sterile syringes equipped with nonrust No. 27 gage, 3/4 inch needles in sterile containers. One is graduated in hundredths for the administration of agents in small dosages. There is an extra supply of needles of various bores and lengths for intravenous, intramuscular, or intraspinal use.

Two sets of equipment for making blood counts are necessary during the winter season when there are so many acute infections and so much sulfonamide therapy is being used. They contain extra slides for making any necessary smears from the nose and throat.

There is a supply of wooden applicators and sterile tongue depressors in paper cases. There are special forceps for introducing Dowling packs into the nose. This celluloid tube contains cotton, some of which is in long fibers for the Dowling pack. This small box contains a number of small and a few large Band-Aids. These Hagedorn needles are very convenient for incising small infections, removing splinters, etc.

My bag contains practically all the important drugs mentioned by Dr. Gold, with some modification and, perhaps, duplication: morphine, codeine, dilaudid, hyoscine hydrobromide, nitroglycerine, atropine, apomorphine, nembutal, seconal, phenobarbital, phenobarbital sodium, delvinal sodium, epinephrine, caffeine sodium benzoate, digitalis, ouabain, quinidine, coramine, a cathartic, aminophylline, pitressin, gynergen, mercupurin, 75 per cent solution of alcohol. I carry several vials of morphine and codeine, inasmuch as I often leave one with a patient. I find it helpful to have 3 bottles of fluid for nasal instillation: one is a 10 per cent solution of argyrol, one a 0.5 per cent solution of ephedrine in saline, and one an oily preparation containing menthol and eucalyptol. I carry three different strengths of adrenalin: a solution of 1:1,000, a solution of 1:2,600, and adrenalin in oil, 1:500. A dose of 0.3 mg. for an asthmatic can be measured more accurately in the more dilute solution of 1:2,600. I carry aminophylline in two forms: one is 0.48 Gm. in 2 cc. for intramuscular injection, and the other a more dilute solution in 10 cc. for intravenous use. I see a number of women who have profuse and prolonged menstrual flow to whom I give testosterone. The one I have at the present time is Oretone, containing 25 mg. per cc. I also carry some ampules of sterile water, as there are times when sterile water is not readily available.

Another thing which I think is important is that you have in your bag a book which lists the things you may need for prescriptions. I always carry a card of metric equivalents. Although I know them perfectly well, they do not roll off my tongue as easily as grains do, and I cannot talk in grams to patients whom I take care of on the outside.

There is a fountain pen and pad for prescriptions, and a few formulas of prescriptions which I use but do not remember. I also have a list of suggestions for diets with the caloric equivalents. I find it very helpful to sit down with the patient who has no appetite and run over the names of a few appetizing foods.

On the other side of the book I keep the record of the patients whom I see each day so that at the end of the week the secretary or I can sit down and summarize the treatment which the patients have received during the week that has passed.

This is a complete list of the contents of my bag.

DR. WHEELER: Dr. Anderson, would you tell us how a pediatrician's bag differs, if it does, from that of a practitioner who takes care of adults?

DR. A. F. ANDERSON: I did not bring my bag. The pediatrician seldom encounters the acute cardiac failure and coronary thrombosis that are so common to physicians who treat adults. We do, however, often encounter some acute situations and for that reason we usually carry adrenalin, not only 1:1,000 but also 1:100, which we can use in an atomizer in case of severe urticaria or other so-called allergic conditions. We also carry some oral stimulant. I carry coramine, and, of late, since I got caught in a rather tight position a year ago, some aminophylline for intravenous use. We see a great deal of asth-

matic bronchitis, sometimes of a very severe type, and the only thing that seems to relieve some of these patients is aminophylline, a dose of 5 cc. repeated in an hour if necessary. We also carry codeine in some form, usually 1/4 grain hypodermic tablets, which can be given, of course, by mouth if necessary but also by injection when the indication is present.

We also carry some sulfathiazole because so many times we encounter—as, for example, at 4:00 A.M. today—a child with a severe acute laryngitis, so-called spasmodic croup, with great difficulty in breathing which was not relieved by the usual procedures of steam, etc. Even before I made the blood count in that case I gave him some sulfathiazole by mouth.

Ipecac, which you mentioned, Dr. Gold, for the so-called croup, is important. A pediatrician cannot be without the syrup of ipecac. It is the best emetic that we have and is usually given in doses of 1/4 to 1/2 teaspoonful, depending on the age of the child. If a quarter of a teaspoonful does not work, then in half an hour repeat that dose in order to induce vomiting, and there will be relief of the laryngeal spasm.

We encounter a great deal of otitis media, much more than one does in adult patients, and I always carry ethyl chloride and a small open mask. If you are caught in the middle of the night, and the otologist, if you are fortunate enough to get one, does not have the ethyl chloride, you have it. We are obliged to open ears ourselves quite frequently. Fortunately we have not lost the art entirely. So in addition to the array which closely resembles Dr. Guion's we carry, and perhaps you do, myringotomy knives, and also a small case with curettes and cotton carriers, and whatever is necessary for the proper care of the ear.

I would not be without the blood counting apparatus. It is even more important for children than for adults if the sulfonamides are to be used.

I carry merthiolate and alcohol, and, as a general rule, some silver nitrate sticks. One often sees small babies just home from the hospital, with granuloma of the umbilicus, or similar conditions, for which the silver nitrate is very useful.

Another condition which we encounter quite frequently at night is a convulsion. We have to be prepared to do lumbar punctures, and so we carry lumbar puncture needles of various sizes. For the small infant the needle is 2 inches long and of very small caliber.

In addition, we have, of course, the intravenous needles or syringes.

The thing that really differs, I think, from the adult practice, is the need for parenteral fluid which we are called upon to administer. No bag—even Dr. Guion's, which was packed so carefully—can possibly carry everything that one needs for parenteral fluid, so I have in the back of my car another old bag which has a 500 cc. vial of 10 per cent glucose and a 500 cc. flask of saline. Equipped with that, we are ready to take care of severe ketosis and repeated vomiting. I think that is the main difference.

DR. WHEELER: Dr. Barr, you have been taking notes. Were they all criticism? Have you some comment?

DR. DAVID P. BARR: I have learned a great deal this morning.

DR. WHEELER: We seem to slight the people in the back rows in favor of the front row, and I should like to know first if any of the students or house officers have any questions about what has been said here today.

DOCTOR: What simple reagents for chemical tests might be carried in the bag?

DR. WHEELER: Dr. Guion, would you like to answer that?

DR. GUION: I often have some crystals of sodium citrate in my bag which I can use in drawing blood for blood chemistry.

STUDENT: Anything for urine examination?

DR. GUION: I have a convenient little packet which I carry with me if I have a diabetic, with which I can do a urinary sugar very easily. I use urotropin for heating the tube. Eli Lilly supplies the unit. It does not cost very much. I do not carry any other reagents for urine examinations.

DR. GOLD: I should like to ask Dr. Guion whether she has ever encountered in her practice a case of diabetic coma or insulin shock? Is it necessary to be prepared for these?

DR. GUION: I have encountered insulin shock fairly often, but I have never seen a case in which I could not pour sugar in the patient's mouth. It is impossible to carry everything in your bag, and sugar is in every household. Diabetic coma I have seen once or twice during the past two years. I have usually immediately brought such patients to the hospital in my car. I found it more sensible than attempting treatment at home.

DR. WHEELER: Dr. Shorr, you had a question?

DR. EPHRAIM SHORR: The question I had has already been raised and answered by Dr. Guion. It was with respect to the little boxes which contain all that you need for sugar determination. It is too bad that the tests for acetone require strong acetic acid and strong ammonia, but it is possible to get small bottles that can be rendered leak proof, and a small amount of each of those with crystals of nitroprusside of

sodium will help a great deal in cases in which you cannot smell acetone on the breath.

DR. WHEELER: I should like to ask you a question, Dr. Anderson. Do pediatricians nowadays carry anything with which to do a tracheotomy?

DR. ANDERSON: Not as a rule. We usually rush the patient to the hospital.

DR. WHEELER: I have one thought, Dr. Gold, about one of the points you mentioned. I think that if a doctor carries a Levin tube and a large syringe in his bag, there are drugs he can do without. He can catheterize the patient if necessary. He can give comatose patients sugar by stomach even if they cannot swallow, and if a patient has taken poison he can wash out the stomach.

DOCTOR: None of the practitioners mentioned magnesium sulfate, which is very useful in convulsions. Why don't they carry that?

DR. WHEELER: Dr. Guion or Dr. Gold, do you have any comments?

DR. GOLD: It seems to me that most of the problems of convulsions are taken care of pretty well by a few whiffs of ethyl chloride. Ether would be safer, but if ethyl chloride is at hand it would suffice. The same can be accomplished by an intravenous injection of phenobarbital sodium, the ampule I spoke about, if the convulsions are not too severe.

I should like to ask Dr. Anderson this: There seems to be a fairly good representation of proprietary samples in the bags and one of them in a great many of these bags. I think I heard Dr. Guion say that she had it too—namely, coramine.

DR. GUION: Yes.

DR. GOLD: What is it there for?

DR. ANDERSON: I have had coramine in my bag for about the past five years, and I have not used it.

DR. GOLD: Is that true for you too, Dr. Guion?

DR. GUION: I seldom use it. All anesthetists carry it with them. If I go to an operation and the anesthetist happens to ask me for an ampule of coramine, I can produce it.

DR. WHEELER: I should like to ask you why you put ouabain into the ideal bag rather than an ampule of Digitaline Nativelle for intravenous use?

DR. GOLD: I can see no objection to having Digitaline Nativelle for intravenous use. I think that at the present time few physicians are accustomed to its use. I myself should prefer to have the same preparation for oral and for intravenous use. This is especially valuable since this material can be given in the same dose by the two modes of administration.

DR. MCKEEN CATTELL: Is the speed of action a consideration in connection with intravenous digitalis medication?

DR. GOLD: The difference in the speed is not often significant. Ouabain, however, does act more quickly.

DR. WHEELER: I have just one other comment to make in relation to a point that was not brought up this morning. I saw two patients in the hospital with tension pneumothorax whose lives were unquestionably saved by the fact that it was possible immediately to insert a large needle into the chest and take off some air. I have always carried a needle with a stopcock, and a syringe for that purpose, because that is one of the most dramatic things one can do. It is just like giving glucose to patients in insulin coma.

DR. JANET TRAVELL: I wanted to ask Dr. Gold if he would prefer the sulfanilamide powder to any other sulfonamide for instillation into wounds for local therapy? I think you mentioned sulfanilamide.

DR. GOLD: Sulfanilamide is recommended in the *Technical Manual* issued by the War Department in March, 1942. Sulfanilamide appears to cake less than some of the others.

DR. WHEELER: As one particularly interested in the sulfonamides, I would take strong exception to the average practitioner burdening himself with some sulfanilamide powder with the idea of putting it into wounds indiscriminately.

I think it is an uncertain procedure.

DR. CATTELL: It is done in the Army.

Summary

DR. GOLD: The discussion this morning indicates that the doctor's bag seems to be in need of more serious attention than it commonly receives if it is to enable the physician to meet the majority of emergencies for which he may hope to be prepared. Samples of proprietary medicines seem to have unduly heavy representation in many bags. We have drawn up a list of medicinal agents for the bag, for the most part essential in meeting the chief emergencies. Heavy bulk and large numbers do not describe this list. Discrimination in choice is the deciding factor.

Case Report

ACUTE DYSPNEA IN A CASE OF CARCINOMA OF THE STOMACH

AUGUSTUS B. CHIDESTER, M.D., F.A.C.S., Auburn, New York

MRS. P. W., age 34, was admitted to the Auburn City Hospital on December 16, 1942, complaining of a sudden, severe pain in the chest and upper abdomen. She also suffered from dyspnea, which had been increasing in severity since the onset of a cold six weeks before. She was in the sixth month of pregnancy.

She gave a past history of typhoid fever at the age of 10, with frequent colds and intermittent gas pockets in the right lower quadrant for the past three or four years. During the last two months she had had occasional spotting, together with pruritus. She had also suffered an attack of appendicitis two and one-half months before. Menstruation had begun when the patient was 15 years old, with a cycle of from twenty-eight to thirty days, seven days' duration, and moderate flow. She suffered slight pain on the first day. L. M. P. occurred on June 5, 1942, and the due date was March 23, 1943. A Wassermann test was negative.

Physical examination revealed an extremely sick woman, gasping for breath. Respiration ranged between 30 and 40 per minute. The heart and lungs were apparently normal. A mass about 6 cm. below the costal margins in the upper abdomen was observed. This mass was palpable in each upper quadrant. In the lower abdomen there was a six months' pregnancy, with the fetal heart audible about 3 cm. below the umbilicus. The cervix showed marked erosion, and Trichomonas vaginalis was present in the discharge. The glandular system was negative. An x-ray of the chest was normal.

The consultant's notes read: "Distended, tense abdomen; spasm in the upper right quadrant. No palpable masses. Unable to hear fetal heart. Question of abscess in the upper right flank."

The patient ran a normal temperature, but her blood pressure increased from 128/78 on December 16 to 140/80 on December 21. Nonprotein nitrogen increased from 30, on December 17, to 40, on December 21. White blood cells increased from 22,900 to 29,700 over the same period of time. The urinalysis was as follows: specific gravity, 1.032; albumin, moderate; sugar, none. Microscopic examination revealed hyaline and granular casts and occasional white blood cells.

The most marked symptom in the patient was her extreme difficulty in respiration. The treatment was symptomatic. Her toxemia increased rapidly, and she died at 11:00 A.M. on December 22.

The diagnosis was (1) severe toxemia, (2) possible appendiceal or subdiaphragmatic abscess, with the appendiceal abscess being favored, and (3) malignancy of the liver.

Autopsy findings showed the liver to be tremendously enlarged and covered with pinkish nodules of various sizes. The stomach was demonstrated. On the greater curvature was a large contracted area, which on being palpated revealed a nodular mass that extended into the stomach.

Diagnosis

1. Carcinoma of the stomach with metastasis to the liver and the adjoining glands.
2. Six months' pregnancy.

120 Genesee Street
Auburn, New York

TOOTH DECAY VACCINE

A vaccine against tooth decay is being tested at the Army Medical Center in Washington, D.C. The vaccine is made from lactobaccilli, the kind of germs believed responsible for decay, Captain Ned Williams, formerly of Dayton, Ohio, explained at the center's dental laboratories.

Both living and dead germs and a combination of the two are being tried in the hope of building up resistance to the germs. After guinea pig tests showed that the vaccine was not irritating, 14 enlisted men, as well as Captain Williams, volunteered to serve as human guinea pigs for further tests of the vaccine. Results will not be known for some time.

Use of chrome cobalt alloy and a new material, methal-methacalat, as substitutes, respectively, for gold and for vulcanized rubber in making soldiers' false teeth, was announced by Major Robert M. Appleman, director of the central dental laboratory at the Army Dental School.

The new metal alloy does not tarnish in the mouth and is made to resist strain. It is used for the plates into which the false teeth are set. Some 30 to 40 a month are made at the Army Dental School. Since the Army dental standards have been revised to take in completely toothless men, the business of making plates and false teeth is booming. The dental school with a staff of 47 technicians made 2,150 plates in one month, most of them with the methal-methacalat base instead of vulcanite.

Besides supplying full and partial sets of false teeth, the Army supplies single teeth when necessary. All are supplied to order and specifications from the dental officers in the field. A stock of 70,000 individual teeth of different colors, shapes, and sizes is kept at the center. All the metal alloy plates for the Army in the eastern half of the United States and the Atlantic bases are made there, those for the western half of the country and the Pacific bases being made at the dental center at Fort Sam Houston. The more frequently used plates, with methal-methacalat base, however, and the teeth for them are supplied from the center in Washington for only the three eastern service commands.—*Science News Letter*

Case Report

Pneumonectomy for Bronchiectasis Associated with Complete Thoracoplasty for Mixed Empyema and Complicated by Pulmonary Tuberculosis

CHARLES W. LESTER, M.D., New York City

PNEUMONECTOMY for tuberculosis has been reported by numerous authors whose success, while dramatic in some instances, on the whole has been disappointing. Pneumonectomy for bronchiectasis with tuberculosis as a complication is sufficiently uncommon so that the following case report should be of interest, especially inasmuch as it reflects the change in the method of treatment of bronchiectasis during the past twenty years.

Case Report

The patient was a white woman, 22 years old, whose illness dated back to the third year of her life, when she had three attacks of pneumonia. This pneumonia initiated a chronic cough which remained with her during the following years. In 1924, at the age of 4, she had pertussis with exacerbation of the chronic cough.

In 1927, when she was 7 years old, her tonsils were removed because of repeated attacks of hemoptysis. After this she continued to raise as much as 2 ounces of blood a day for two or three weeks and was accordingly admitted to a hospital for study, under the suspicion of having pulmonary tuberculosis. No pulmonary tuberculosis could be demonstrated, however, and she was discharged and remained at home for the next three years, although during that time she continued to have cough, sputum, and hemoptysis.

In 1930 she was admitted to a tuberculosis sanatorium because of hemoptysis and was treated as a tuberculous patient for twenty-nine months, although there was never any positive evidence of tuberculosis by x-ray, sputum examination, or any other of the tests which were employed.

She was discharged from this hospital and returned to her home, but in February, 1934, ten months later, she was admitted to a third hospital because of the continued hemoptysis. X-ray and sputum examinations were negative for tuberculosis, and for the first time a diagnosis of bronchiectasis of the left lower lobe was made. Left pneumothorax was instituted, and she was discharged in June, 1934, to continue her refills as an outpatient.

In February, 1936, she was readmitted to the same hospital because of considerable loss of weight and repeated hemoptysis. At this time x-ray examination indicated a tuberculous lesion in her right lung and one positive specimen of sputum was obtained out of twenty-one examinations. Right pneumothorax was instituted but, because it was ineffectual, was abandoned in three months. Bed rest was maintained until July, 1936, when she was discharged to her home. One month later she was readmitted again because of hemoptysis, but again all sputum examinations were negative for tuberculosis and she was discharged in September, 1936. During the last admission the pneumothorax on the left side was abandoned, but the left lung did not re-expand.

The patient remained at home until August, 1938, when an attack of fever and cough was diagnosed as right-sided pneumonia and she was readmitted to the same hospital. The pneumonia cleared up, but in October, 1938, gastric washings were positive for tuberculosis, and in November, 1938, sputum was positive for tuberculosis on two occasions. Bronchoscopy at this time revealed nothing of importance but was followed by a pulmonary hemorrhage. Fluid was then demonstrated in the left side of her chest, where the lung had failed to re-expand. This condition was treated by aspiration on six different occasions, bloody fluid being obtained each time. On one occasion this was positive for tuberculosis. In September, 1939, a bronchopleural fistula developed on the left side, and the patient raised copious quantities of foul sputum. She was toxic and febrile, and it was necessary to perform a thoracotomy for drainage. The empyema continued to drain, and between March and June, 1940, a complete, eleven-rib thoracoplasty was done in five stages. The thoracotomy tube was removed in August, 1940, and the wound healed.

She was then sent to the New York Municipal Sanatorium at Otisville for the continuation of her treatment. At this time no evidence of active infection was found in her right lung. Her left lung was collapsed under an eleven-rib thoracoplasty, and repeated examinations of her sputum and gastric washings failed to reveal tuberculosis by smear or culture. However, she continued to raise about 100 cc. of bloody sputum a day and on numerous occasions had frank hemorrhage.

In February, 1941, she was transferred to the Chest Service at Bellevue Hospital, New York City. She was bronchoscoped, and in her left lower lobe bronchus granulation tissue was found which did not have the appearance of being tuberculous. Treatment by silver nitrate through the bronchoscope resulted in the healing of this lesion. X-ray examinations, sputum examinations, by culture and smear, gastric washings, and all other tests to demonstrate tuberculosis were negative. Apparently, her tuberculosis was well controlled. Lipiodol injection in the left lung showed puddling indicative of bronchiectasis, but a bronchogram of the right lung was normal. This, together with the bronchoscopic examination, showed that her symptoms were all coming from her collapsed left lung and that the only hope of relieving her from a life of chronic invalidism was removal of the left lung. The hazards of the operation were explained to her, and she was willing to take the risk.

Accordingly on July 15, 1941, left intrapleural pneumonectomy was performed. The thoracoplasty scar was reopened, and because of the regenerated ribs, there was considerable difficulty in entering the chest. The initial opening was made well posterior in order to avoid the pericardium. This proved to be a wise move because entrance to the chest was demonstrated only when lung tissue was incised. By sharp dissection, the dense adhesions were freed and the lung mobilized except for one spot on the diaphragm, one area on the peri-

cardium, and one on the mediastinal pleura where it did not seem possible to liberate the lung without damage to these structures. These attachments were clamped, cut, and ligated, thus mobilizing the lung. A snare was placed about the hilum and the lung was removed distal to the snare. The stump was sutured, further secured by a ligature of heavy silk, and the pleural cavity packed. Since the condition of the patient was decidedly precarious at this time, the chest wound was hastily closed and the patient returned to bed. One liter of 5 per cent glucose and saline and 500 cc. of blood were administered by vein during the operation.

The patient rallied from the operation. Removal of the packing was started on the third day and completed on the sixth. Nausea and vomiting, which had troubled her after the operation, ceased when the packing was removed. A tube was inserted after removal of the packing but bronchial fistula did not develop, and the wound was allowed to close. The pathologic diagnosis was bronchiectasis. The examination failed to show tuberculosis.

The patient continued to have a cough, raising 20 or 30 cc. of frothy sputum, like saliva, every day. Bronchoscopic examination showed that the bronchus was well closed, and a bronchogram indicated that it was rather long, amputation having been made at the division of the stem bronchus into upper and lower lobe bronchi. The sputum apparently comes from this blind pocket. There is a moderate amount of scoliosis as a result of the thoracoplasty. Pulmonary functional tests show that the vital capacity is only about half that of a normal individual, as would be expected, but they also show that it is a little more than it was before pneumonectomy. The oxygen saturation of the arterial blood was normal—higher than it was before pneumonectomy—and the oxygen removal from the inspired air was greater after the pneumonectomy than before.

The patient was discharged from the hospital in September, 1941. After a period of two months' convalescent care she obtained a position in a secretarial capacity, where she now (March, 1943) works eight hours a day. She feels well and is gaining weight, although she still raises 20 to 30 cc. of frothy sputum daily.

This case demonstrates the fact that hemoptysis may result from something other than pulmonary tuberculosis and that artificial pneumothorax is not the treatment for bronchiectasis. Both of these facts are well understood now, but at the time treatment was begun on this patient our knowledge was not so complete as it is today. It is also interesting to note that the onset of this patient's tuberculosis occurred two years after her discharge from the tuberculosis sanatorium.

SALT WATER FOR SHOCK

A drink of salt water, of just the right strength, may become the future first aid treatment for shock in extensive burns.

Experiments at the National Institute of Health by Dr. Sanford M. Rosenthal, principal pharmacologist of the U.S. Public Health Service, point that way, although so far no human trials of the method have been made.

Survival rate for the first two days among burned mice given about one-fourth of a teaspoonful of the salt drink was about twice as high as among the animals not given this drink. When the animals were given two salt drinks, one and four hours after the burn, only about 13 out of 100 died the first day and 17 out of 100 on the second, as compared with about 93 out of 100 that died among untreated controls.

Dr. Rosenthal compared the salt drink treatment for shock from burns with other standard methods of treating shock. No benefit was observed, he reports, from epinephrine (adrenalin), posterior pituitary gland extract, adrenal cortical extract, or a synthetic adrenal cortical hormone preparation.

Human blood serum showed little effect when injected into the veins of the mice. Mouse blood serum was more effective but not so good as the salt drink.

Whether a salt drink can replace blood serum or blood plasma as lifesaving treatment for shock in human victims of burns cannot be told until more experiments have been made. The salt drink treatment is based on a different principle from that of replacing lost fluids as by plasma or blood transfusions, Dr. Rosenthal explained.

In mice, he finds, the acute mortality—that is, death—occurring within a day or two after an extensive burn, is closely related to a disturbance of the balance of sodium and potassium in the body as well as to the escape of fluids from the blood stream.

The upset in the sodium-potassium balance seems the most important, he reports, and may be the cause of the concentration of the blood and other effects attributed to the loss of fluids in the burned areas. Doses of potassium speeded death in the burned mice, and when this was given with sodium chloride, it antagonized the effects of the salt drink.

The strength of the salt drink, he explains, has to be such as not to upset the fluid balance of the body, and should have about the same osmotic pressure as that of the blood.

Since it is the sodium of the salt that is effective, other sodium salts, such as sodium bicarbonate, might be given if the salt drink proved too nauseating.

Salt tablets of the right dose with a glass of water might prove the most practical method for first aid use, if the new treatment develops into one useful for human burn victims.

Further studies on methods of saving those who succumb to burns after the first two days will be made, Dr. Rosenthal says. The studies have so far been limited to effects of treatment for shock, rather than for the burn itself, since in man from 60 per cent to 80 per cent of the deaths from extensive burns occur within the first few days as the result of shock.—*Science News Letter*

RUSSIAN MILITARY MEDICINE

The popular concept in this country is that Russia is a backward nation. This idea is based on what Russia was many years ago, but it would surprise many here to know how modern the Russians are in their medical services, both in peacetime and in war. We shall not discuss the progress they have made in their peacetime handling of the sick and injured, but the recently released statistics of how well the Russians are doing in caring for their wounded in battle are most encouraging.

It is reported that 70 per cent of the wounded are back in combat services. Only 1.5 per cent of the Russian wounded have died. This is but a small fraction of their mortality of the wounded in the last World War, and also considerably better than the German or French figures of the last World War.

It may seem that the Russians have accomplished a miracle but they laid the groundwork for their present-day results some twenty years ago. Then they had only 20,000 physicians. In 1940 there were 160,000 physicians in Russia, and they were graduating about 12,000 new physicians in a year.

Now they are graduating more than three times that number. In the invaded sections where some of their foremost medical colleges were situated, they moved their entire medical schools, including students, laboratory equipment, books and teachers, back into the Urals, hundreds of miles away, where they continued their training without much interruption.

One of the most helpful factors in the Russian setup is the so-called *Feldschers*. This is a group of about 400,000 men and women who are not graduate physicians but who have had considerably more practical training than our advanced first aid groups—training in practical nursing, care, and transportation of the wounded, and those who have worked in close cooperation with physicians. They have enabled the Russians to get in their wounded early and give them first aid and care which is so essential, for the mortality ratio always goes down in direct ratio to the speed with which the wounded receive their first treatment.

The Russians use the sulfa drugs as much as we do. They also make wide use of serums and transfusions.

We believe that the Russian technic is superior to our own in many ways. They have pioneered in this field and have invented many methods of preserving blood which have proved highly successful, and we would do well to take advantage of their technic.—*Medical Record*

ON CARE OF THE NAILS

Right or wrong, the appearance of the nails and hands is often considered as an index of one's character, so consequently care of the nails usually begins at birth, Herman Goodman, M.D., New York, declares in *Hygeia, The Health Magazine*, for May.

"In childhood," he explains, "the problem of nail care revolves about the habit of nail biting. The psychologist claims nail biting is more or less normal. Nearly all mothers discipline the baby who persists in sucking the nail, or the finger tips when the nails are worn down. In any event, a young boy or girl who has a nail-biting habit following the finger sucking of early childhood should have nail care. Some children are freed of the habit by acquiring pride in the appearance of their nails. This may be done by professional manicure, keeping the nail short without free or hangnail edges. . . . . Some people claim to have cured the nail-biting habit by the application of tart or bitter chemicals to the nail or finger extremities. This is not always effective: some children come to enjoy the bitterness or saltiness of the average safe chemical applied for this purpose.

"Nail care at home may be attempted as soon as the child appreciates what you are trying to do. Visits to a professional manicurist will usually do much more than you can."

The question as to at what age colored nails should be permitted, tolerated, or encouraged by parents cannot be arbitrarily answered, Dr. Goodman says, because of marked differences between chronologic age and social age, which depends on many other factors.

Dr. Goodman warns that the fact that various nail lacquers do not conform to any one type of formula or recipe should influence one against attempting to mix nail lacquer cosmetics from two manufacturers and to apply the mixture on the fingernails, and that the same admonition applies against mixing various products from the same manufacturer.

"It is impossible to nourish the nail by an application to its surface," he says. "The appearance of the surface of the nail may be altered by physical or chemical means. The result is always temporary, as the nail continues to grow. Malformations or distortions of the nail surface due to injury of the matrix of the nail can be removed or camouflaged by applications to the surface. . . . .

"The question has often been asked whether or not nails 'breathe.' This is usually a preliminary question to one regarding the effect of nail lacquers on such breathing. The nail does not breathe. . . . ."

Medical News

Army Medical Administrative Officers Trained in Texas

ONE of the most rapidly growing officer corps in the Army is the Medical Administrative Corps, a nonmedical group which is combining its knowledge of supply, evacuation, personnel, and training methods with the specialized work of the professional men.

Noncommissioned men from all branches of the service are chosen by selecting boards and given special instruction at the Medical Administrative Officer Candidate School at Camp Barkeley, Texas. Some of the candidates come from such civilian fields as pharmacy, embalming and mortuary, chemistry, hospital administration, and premedical training.

At the Administrative school, the only one of its kind since Carlisle Barracks, Pennsylvania, was taken over completely by the medical field service, candidates are given intensive training in logistics, tactics, sanitation, administration, chemical warfare, and allied subjects, which will enable graduates to qualify for any job in the Medical Administrative Department.

A class of from 200 to 400 second lieutenants is graduated from the school every two weeks. Commandant of the school is Brig. Gen. Roy C. Heflebower, who is also commanding general of the Medical Replacement Center. His assistant is Col George E. Armstrong, Medical Corps, who has been assistant commandant since the school was founded.

Office of Civilian Defense Expands Rescue Service

WITH British experience demonstrating the importance of a lifesaving service trained in technics similar to those used in mine rescue work, James M. Landis, Director of Civilian Defense, has taken steps to strengthen our rescue service with the appointment of Simon H. Ash as Chief of the Rescue Section of the Medical Division of the Office of Civilian Defense.

Mr. Ash, who also serves as Chief Engineer, Metal and Nonmetal Section, Mineral Production Security Division, U.S. Bureau of Mines, will go to England soon to study rescue technics. On his return he will establish "pilot" schools in Pittsburgh and in the San Francisco Bay area for the training of rescue officers.

Under the present plan, when an incident occurs, the medical adjutant at the Control Center will dispatch an express party to the scene. The express party will include one ambulance, one mobile medical team, and, if trapped casualties are reported, one rescue team sent out by the Chief of Rescue Service. Coordination of the two services will make possible immediate clearance to hospitals of seriously injured casualties recovered from debris.

Annual Session on Physical Therapy

THE American Congress of Physical Therapy will hold its twenty-second annual scientific and clinical session September 8, 9, 10, and 11, inclusive, at the Palmer House, Chicago.

Rehabilitation is in the spotlight today, and physical therapy plays an important part in this work.

The annual instruction course will be held from 8:00 to 10:30 A.M., and from 1:00 to 2:00 P.M. during the days of September 8, 9, and 10, and will include a round-table discussion group from 9:00 to 10:30 A.M., Thursday, September 9. The scientific and clinical sessions will be given in the remaining portions of these days and evenings. A feature will be an hour demonstration showing technic, from 5:00 to 6:00 P.M. during the days of September 8, 9, and 10.

All of these sessions will be open to the members of the regular medical profession and their qualified aids.

For information concerning the instruction course and program of the convention proper, address the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

Emergency Medical Service in Industrial Plants

EVERY industrial plant medical department should prepare a "disaster operations plan" to provide adequate medical service in case of a plant catastrophe involving large numbers of casualties.

This is the advice given in the new bulletin, *Emergency Medical Service for Industrial Plants*, issued by the Medical Division of the Office of Civilian Defense.

The plan should provide for necessary first aid care at the site of the incident, for adequate ambulance service, and for hospitalization of the seriously injured.

Casualty stations must be set up, with arrangements made for alternative locations that may be used if those of first choice are destroyed.

Accurate records should be made for every person, injured or uninjured, who leaves the plant, and the place to which the injured have been taken should also be given. Casualties should be distributed among various hospitals in order to guarantee quick and efficient service.

County News

Broome County

Dr. Clarence E. Bolton, former federal meat inspector at Albany, was recently appointed chief health inspector of the City of Binghamton, to succeed the late John L. Costello.*

Cattaraugus County

At the annual dinner meeting and election of officers of the county society, held Thursday evening, June 10, in Hotel Dudley, Dr. J. A. Taggert, of Salamanca, succeeded Dr. Henry Allen, of Gowanda, as president of the organization.

Other officers elected were: Dr. M. G. Sheldon, of Olean, vice-president, to succeed Dr. Taggert; Dr. W. R. Ames, of Olean, secretary and treasurer, to succeed Dr. Leo E. Reimann, of Franklinville.

Dr. Herbert H. Bauckus, president-elect of the Medical Society of the State of New York, attended the meeting and addressed about 30 doctors on tentative plans of the State Department of Health to furnish obstetric care for soldiers' wives.*

Chautauqua County

Dr. and Mrs. William A. Randel, formerly of Mt. Vernon, have arrived in Jamestown, where Dr. Randel has opened an office to practice as a specialist in ear, nose, and throat work.

Before his move, Dr. Randel had practiced at Mt. Vernon for the past twenty-seven years and prior to that had practiced in New York City. He is a diplomate of the American Board of Otolaryngology, a fellow of the American College of Surgeons, a fellow of the American Medical Association, member of the Westchester County Medical Society, and former treasurer of the Mt. Vernon Medical Society. He was formerly connected with the Manhattan Eye and Ear Hospital and the New York Post-Graduate Medical School.*

* * *

Chautauqua County's quota of doctors for the armed forces has been filled, an announcement at the meeting of the county society on June 18 at the White Inn, Fredonia, showed.

The main speaker at the meeting was Dr. James C. Sullivan, professor of surgery at the University of Buffalo, who addressed the 35 doctors present on "Peptic Ulcer Surgery."*

Cortland County

In the thirteenth annual report of the Cortland County Health Department, Dr. William E. Mosher, Jr., commissioner, records a series of accomplishments in community health for the year ending December 31, 1942, despite shortages in personnel and other handicaps occasioned by the war.

The report gives first place in the list of achievements to an intensive diphtheria immunization drive which resulted in the protection of 753 preschool children, raising the Cortland city immunization rate from 29 per cent in 1941 to 47 per cent in 1942, and the rest of the county from 36 per cent to 45 per cent in 1942. This was more than twice the preschool immunizations completed in any single year since 1938.

Among other accomplishments were organization and utilization of volunteers in such work as making surveys, assisting at clinics, and preparing supplies; immediate hospitalization of all newly discovered active tuberculosis cases; establishment of an emergency public health nursing service; and inauguration of a dental program in connection with the preschool consultation service.—*Health News*

Dutchess County

The Dutchess County Health Association plans to improve its health program for the coming year by the addition to its staff of a full-time trained health educator who may place special emphasis in the nutrition field and aid toward the development of a permanent home bureau, according to the association's twenty-seventh annual report.

The association also aims to prepare, by expenditure of funds and general development, for a dental clinic.

The association's full-time year-round health education program in tuberculosis receives added stimulus at the time of the Christmas Seal sale and in April during the early diagnosis campaign. The association has endeavored to reach the school population through the Christmas Seal health programs and in the past year has given special attention to the distribution of materials to the factories by means of its bulletin board poster service as well as by payroll pamphlet distribution.

The association has acted for several years as substitute for a Women's Field Army in Dutchess County and has given the necessary contribution in funds to the New York State Cancer Committee. It has been copartner with the cancer committee of the county medical society in health education. Considerable literature has been distributed and articles have been written concerning cancer.

By means of the association's Children's Treatment Fund, considerable dental correction has been accomplished and this program and its facilities are still available. More recently, through participation with the Dental Committee of the Dutchess County Welfare Council, the association has given thought to Poughkeepsie's school dental program and the possibility of the establishment of an enlarged adult clinic at Vassar Hospital.*

Erie County

Steps to relieve the critical shortage of doctors in the Tonawandas were considered at a meeting on June 24 of the War Councils of Tonawanda and North Tonawanda in joint session with the Twin Cities Academy of Medicine.

As a result of military enlistments and recent deaths among physicians, the ratio now is only one doctor to 3,000 persons. The two cities have lost 17 doctors to the armed forces, and several elderly doctors are unable to maintain active schedules.

The War Council and the Academy discussed the advisability of three proposals: (1) discourage further enlistment of medical men in the Tonawandas; (2) attempt to have one or more doctors released from military duty and returned to private practice; and (3) bring new doctors into the cities if possible.

Similar attempts to relieve the shortage of physicians in Buffalo are being made by the county medical society through the development of a plan

* Asterisk indicates that item is from local newspaper.

that will help residents of Buffalo and Erie County to obtain medical attention.

Doctors in the city have been organized by wards and, outside the city, by towns. Patients will call the society between 9:00 A.M. and 5:00 P.M., or the Nurses' Registry between 5:00 P.M. and 9:00 A.M., and a doctor will be recommended. According to Dr. Harold F. R. Brown, president of the society and originator of the plan, the doctors have cooperated very well and have taken increasing numbers of patients in spite of heavy demands upon their time.

Jefferson County

The county society, at its regular monthly meeting on June 15, passed a resolution favoring a county health organization and recommending to the mayor, the city council, and board of supervisors that such a department be established.

The society also requested the appointment of the various officers necessary in the organization of a county health department: a county health commissioner; county deputy commissioners, probably 8 to 10; county health nurses, probably 16 to 18, at least one for each town in the county, all serving under a supervising nurse; county veterinarian and county sanitary engineer; and the establishment of a county laboratory.

The speaker at the meeting was Dr. Floyd S. Winslow, of Rochester, whose subject was "Interesting Medicolegal Cases."*

Kings County

Dr. Joseph Lo Presti, assistant surgeon, United States Public Health Service Reserve, and a member of the staff of Long Island College Hospital during the past two years, has been assigned to the National Society for the Prevention of Blindness to carry on a program in the field of industrial eye hygiene, it was announced recently by Mrs. Eleanor Brown Merrill, executive director of the society.*

Monroe County

Appointment of a 24-member medical advisory panel for the Monroe County Rationing Board to pass on applications for rationed commodities based on medical necessity has been announced by Joseph D. Patterson, district OPA manager, and Dr. D. C. Padelford, board chairman.

The panel is headed by Dr. G. Kirby Collier, as general chairman, and is divided into three groups of 8 physicians recommended by the Monroe County Medical Society, the Rochester Academy of Medicine, and the city and county war councils.

The groups and their personnel are as follows:

Group One: Dr. B. J. Duffy, chairman; Dr. H. B. Crawford, Dr. L. T. Waldo, Dr. S. R. Snow, Dr. P. W. Beaven, Dr. C. W. Warren, Dr. D. A. Haller, and Dr. C. S. Lakeman;

Group Two: Dr. A. D. Kaiser, chairman; Dr. H. H. Baker, Dr. J. J. Finigan, Dr. J. L. Van de Mark, Dr. H. I. Norton, Dr. E. H. Burnes, Dr. G. E. Sanders, and Dr. C. I. Maggio;

Group Three: Dr. C. B. F. Gibbs, chairman; Dr. J. P. Henry, Dr. E. G. Whipple, Dr. G. K. Collier, Dr. J. K. Quigley, Dr. David Wolin, Dr. L. C. Boynton, and Dr. F. S. Winslow.*

• • •

The 400th anniversary of Andreas Vesalius' disclosure of new theories in anatomy was marked at the Rochester Academy of Medicine on Wednesday, June 16.

Dr. Charles B. F. Gibbs, president of the academy, presided at the special meeting, and the principal speaker was Dr. Ernest Sigerist, professor and director of the Institute of the History of Medicine at Johns Hopkins University. His topic was "The Contributions of Vesalius to Medicine."

There was also a special exhibit of Vesalius material arranged by Dr. John R. Williams, of the Academy Museum. Members of the Women's Auxiliary of the Academy, headed by Mrs. Christopher G. Parnall, were hostesses at a buffet supper at 6:30 P.M. on the academy lawn preceding the meeting.*

New York County

Direction of all medical teaching in the New York Eye and Ear Infirmary was taken over by the School of Medicine of Columbia University on July 1, it was announced recently by Dr. Robert M. Youngs, president of the infirmary, and Dr. Willard C. Rappleye, dean of the Columbia school.

The directors of the infirmary, it was said, had decided that medical teaching controlled by the standards of a large university medical school could develop more effective training programs to cope with war casualties and expansion of research.*

• • •

Schuman's, 20 East 70th Street, has issued under the title "Rare Medical Books" its eighth catalogue of materials important in the history of medicine. A strong element in the present catalogue of nearly 500 titles is the group of 99 titles which are divided into works by Vesalius, works incorporating in part Vesalius's illustrations or writings, and general medical works of the Renaissance. The remainder of the catalogue comprises miscellaneous medical works of many periods. The publication of such a catalogue is an event for the medical collector.*

• • •

The number of syphilis cases reported to the New York Health Department in 1942 showed an increase of 10 per cent over 1941, according to an annual report of the Bureau of Social Hygiene, released recently by Health Commissioner Ernest L. Stebbins.

The number of all reported venereal disease cases increased from 40,311 in 1941 to 42,925 in 1942.

"Of particular significance was the increase in the reported cases of syphilis among boys and girls between 15 and 20 years of age," said Dr. Theodore Rosenthal, director of the Bureau of Social Hygiene, who prepared the report. "Primary and secondary syphilis in this group showed a rise of 37 per cent for the year 1942 as compared with the period 1939–1941."

It was pointed out that from the inception of The Selective Service Act, through December 31, 1942, the Department's diagnostic laboratory examined 893,281 specimens for syphilis and the percentage of registrants with positive serologic reactions was estimated to be 2.5 per cent. All registrants suspected of having a venereal infection were followed up for further examination.

"The widespread use of blood tests in selective service, premarital, and prenatal examinations has created a vast case-finding project for the study of

venereal diseases in the New York area," the report said.

Dr. Rosenthal reported that last year the Health Department tested a total of 640,230 selective service blood specimens, or nearly three times as many as in 1941. In addition, 176,105 premarital serologic tests for syphilis were recorded. As a result of these tests, there was a substantial increase in the number of "venereal disease suspects" examined, diagnosed, and treated. Following treatment many were able to enter the armed forces or to return to their normal occupations.*

• • •

With the issuing on June 24 of the *Directory of Tuberculosis Clinics*, published annually by the New York Tuberculosis and Health Association, Dr. J. Burns Amberson, Jr., president of the Association, announced that there are 42 tuberculosis clinics operating at the present time in the City of New York.

Compiled under the direction of Dr. H. McLeod Riggins, chairman of the Tuberculosis Committee of the New York Tuberculosis and Health Association and Medical Director of Triboro Hospital in Queens, the directory provides identifying information on the 26 officially designated district clinics and the 17 nondistrict clinics which serve the five boroughs of New York City. Of the 42 tuberculosis clinics, 19 are located in Manhattan, 6 in the Bronx, 8 in Brooklyn, 7 in Queens, and 2 in Richmond; 20 are under the supervision of the Department of Health; 11 are under the supervision of the Department of Hospitals; and 11 others are supervised by voluntary hospitals and agencies.

Diagnostic services are available at 35 clinics; pneumothorax treatments may be obtained in 17 clinics, 10 operated by the Department of Hospitals, 6 by voluntary institutions, and one by the Department of Health. There are 23 consultation clinics in the city, 19 of which are operated by the Department of Health and 3 by the Queensboro Tuberculosis and Health Association. Twenty clinics have evening sessions, and 8 conduct separate sessions for children. The Department of Health maintains a survey clinic, and Montefiore Hospital, a voluntary institution in the Bronx, has a tuberculosis-diabetic clinic.

The directory includes also maps showing the boundaries for the tuberculosis district clinics and lists the branch offices of the Department of Health and the District Health Centers, with identifying information.

• • •

Saul M. Small, M.D., has been appointed to the staff of the National Hospital for Speech Disorders as psychiatrist and assistant to the Medical Director. Dr. Small was formerly a resident psychiatrist at the Payne Whitney Psychiatric Clinic.

• • •

First Lieutenant Margaret Janeway was discharged from the Women's Army Auxiliary Corps to become a major in the Army Medical Corps—the first woman to become an Army doctor in the North African theater and the second in the entire United States Army.

Her transfer gratified a long-standing ambition. She had practiced extensively in New York City at the Lenox Hill and St. Luke's Hospitals. Major Janeway's grandfather, Colonel John H. Janeway, was an Army surgeon in the Civil War, and she always wanted to follow his career.

She became a contract surgeon assigned to the W.A.A.C. on October 21, 1942, later deciding to join the organization, and was sent abroad with the first W.A.A.C. company in North Africa six months ago. She then applied for a Medical Corps commission.

Major Janeway was born in Trenton, New Jersey, and received her education at Bryn Mawr, Columbia, and the College of Physicians and Surgeons in New York City.

• • •

The United Seamen's Service announced last week that it would broaden its entire medical program and establish new centers where seamen may convalesce after injuries or illness and where those unable to return to their old duties may be instructed in new work and given new interests.

A new occupational retraining center is to be set up in New York City for merchant seamen incapacitated for their old duties, and a suitable building for this purpose is now being sought, Douglas P. Falconer, national executive director of the service, said. He listed other objectives as follows:

To install proper medical chests and medical books on all merchant ships; to give courses and show movies on health topics to officers and men, to establish a uniform system of physical examination of seamen by shipping companies, to meet all seamen-survivors of war action on their arrival home and see that their medical needs are met, and to publish special books and pamphlets on health topics for seamen.*

• • •

Six deaths from heat prostration and increases in mortality from diseases common to old age—in which unusual heat might have been an important factor—raised the general death rate in New York City for one of the recent hot weeks to 11.9 per 1,000 population, Health Commissioner Ernest L. Stebbins reported. The death rate in the preceding week was 10.3.

So far this year deaths have averaged 11.5, compared with 10.2 at this time in 1942 and 10.7 in 1941. A somewhat higher death rate in wartime is to be expected among the civilian population, health officials pointed out, adding that the picture was distorted somewhat by removal of youths into the armed services—and therefore out of the reportable vital statistics except as part of the basic population.*

Niagara County

A physician pooling plan for night calls and emergencies was outlined by Dr. Richard H. Sherwood in an address to the Niagara Falls Rotary Club in the Hotel Niagara on June 14. Dr. Sherwood discussed the project from various angles, setting forth the advantages which would result from adoption of the plan.*

Oneida County

When the county society met on July 13, it discussed the action of the American Medical Association, taken June 9 in Chicago, to create a new

council to plan for better medical care throughout the nation.*

• • •

Dr. F. M. Miller, Utica deputy medical officer for Civilian Defense, called a meeting for all members of the Emergency Medical Corps, Civilian Defense, on Wednesday, June 16.

The program included a sound movie, "Fighters in White." There was discussion of emergency medical service by Col. A. J. Canning, director of Rhoads Hospital. Colonel Canning was in charge of a service hospital at Pearl Harbor, December 7, 1941.

A round-table discussion by the adjutants followed.

Information on the subject of emergency, medical technic and chemical warfare was given. Chemical Warfare Director G. W. Pirk, Dr. Fred Owens, and Dr. F. M. Miller, Jr., took part in the discussion.*

• • •

The newest addition to the staff of the Army Air Forces Technical Training Command in charge of more than 350 premeteorologic trainees at Hamilton College is a full-time Army physician, Lt. Conrad E. Rosdahl.

Establishment of a dispensary in the Hamilton College gymnasium will be supplemented by use of the Rome Air Depot Hospital, Lieutenant Rosdahl indicated.

A graduate of Cornell University, Lieutenant Rosdahl received his medical degree from the College of Physicians and Surgeons at Columbia University and interned for a year at Sacred Heart Hospital, Spokane, Washington, before entering the Army.*

Ontario County

The regular quarterly meeting of the county society was held at the Geneva Country Club, Tuesday, July 13.

The three addresses on the scientific program, which was furnished by the staff of the U.S. Naval Hospital, Sampson, New York, included: "Experiences with the Medical Department on Guadalcanal," by Chief Pharmacist J. Scripp, Jr., USN; "Experiences on a Hospital Ship in Pearl Harbor," by Lieut.-Comdr. J. D. Norris (MC), USNR; "The Importance of the Bacteremic Phase of Cerebrospinal Fever and Its Relation to the Waterhouse-Friederickson Syndrome," by Lieut.-Comdr. F. R. Bailey (MC), USNR.

Orange County

Dr. Arnold S. Banks has returned to Newburgh after spending two years in Kings County Hospital, Brooklyn, where he completed a surgical internship and was resident surgeon in fractures.

Dr. Banks has now opened his office for the general ractice of medicine.*

Putnam County

The Putnam County Welfare Department now has a County Medical Plan, whereby services to welfare clients are rendered in accordance with the prescribed rules.

The plan calls for a medical consultant to the welfare department, and at a recent meeting the board of supervisors appointed Dr. Robert S. Cleaver, of Brewster, as county medical consultant. His appointment had been recommended by the County Medical Association.

Steuben County

Meeting June 10 at the Wagner Hotel in Bath, members of the county society voted to continue the Farm Security Administration rural medical care plan for another year in Steuben County. Dr. R. D. Haggerty, of Arkport, chairman of the rural medical care committee, reported on the workings of the plan.

A paper on the subject, "Sesame and Peanut Oil Cysts," was given by Dr. R. J. Shafer, of Corning. At the New York State Association of Public Health meeting held in Albany June 25, Dr. Shafer again spoke on this subject, on which comparatively little research has been done as yet.

A report of the nonprofit medical insurance plan now under discussion was given by Dr. Shafer, speaking on behalf of Dr. George Taylor, of Hornell, chairman of the committee for investigating the plan. It was decided that the committee should further consider the plan and report again at the next meeting.

Dr. H. B. Smith, of Corning, delegate of the first district of the county, and Dr. W. J. Tracy, of Hornell, delegate of the second district, reported on the State meeting held recently in Buffalo.

Reports were given by Dr. John Conway, of Hornell, district state health officer and chairman of the public health committee, and Dr. C. M. Lapp, of Corning, chairman of the committee on war participation.*

Suffolk County

Dr. William H. Ross, of Brentwood, observed his fifty-fifth anniversary in the practice of medicine on June 1. He began his internship at the Presbyterian Hospital in New York City on June 1, 1888, after graduating from Columbia University. Dr. Ross was recently elected chairman of the Board of Trustees of the New York State Medical Society. He has already served two terms as a trustee of the State Society.*

Westchester County

Dr. Ebba A. Dederer, Chief of the Division of Medical Inspection, of the Department of Public Instruction, began a year's leave of absence due to ill health on June 23. She will go to her ranch at San Diego, California. During Dr. Dederer's administration it is estimated that the school student group has averaged 11,000 annually, which represents 200,000 units of total annual attendance guarded by the school system's health service.*

RESULTS OF HOSPITAL TREATMENT OF NARCOTIC DRUG ADDICTS

A thorough, well-organized follow-up study has been made of 4,766 male patients discharged from the United States Public Health Service Hospital at Lexington, Ky., during the period from January 1, 1936, to December 31, 1940. All these patients had received treatment in the hospital for addiction to narcotic drugs. The only narcotics mentioned in the report are opium and its derivatives. The follow-up was carried out between July 1 and December 31, 1941: in other words, at least six months after the discharge of the last patient in 1940.

The results of the follow-up are presented in detailed tabulations, which are analyzed and discussed from various points of view. The patients fall into four general classes: voluntary, probationer patients, paroled prisoners, and prisoner patients. A probationer patient is a narcotic drug addict who, for violation of a federal law, has been given a probationary sentence on the condition that "he goes to one of the United States Public Health Service hospitals either at Lexington or Fort Worth for treatment and remains until pronounced cured by the medical staff."

The state as to addiction of 39.6 per cent of the 4,766 discharged patients could not be determined, 7 per cent had died after leaving the hospital, 29.9 per cent had relapsed to the use of drugs, and 13.5 per cent were still abstinent. Excluding the dead and the unknown, 74.7 per cent had relapsed and 25.3 per cent had remained abstinent.

The analysis of the facts about the different classes of patients led to the important conclusion that the most successful program of treatment for narcotic drug addicts includes a comparatively short period of hospitalization, not less than two months but not more than five, with acceptable employment as a prerequisite for release, and then adequate extramural supervision for three years with periodic check-up examinations. This means that for patients placed on probation for three to five years the one innovation necessary to carry this program into effect would be compulsory employment. Periodic check-up services have been initiated at the Lexington hospital. The general belief that a drug addict can never be cured is not supported by this follow-up study.—*J.A.M.A.*

NEW EMERGENCY COMMUNICATIONS SYSTEM SET UP

Through the cooperation of the Office of Civilian Defense and the Federal Communications Commission, an important aid for defense forces, the War Emergency Radio Service, has been set up. This offers a system of two-way radio communication, operating on three bands of several channels each, so that there is no practical limit to the system's flexibility.

One band connects the local Civilian Defense control center with the district control center; a second band connects the local control center with local fixed points such as wardens' posts, fire houses, hospitals, public utilities, and industrial plants; and the third band connects mobile forces, like fire trucks and emergency medical teams, with the control center.

This band can likewise be connected with walkie-talkies.

The communicating range of the WERS system is approximately 10 miles, a range limited enough to be useless to the enemy but valuable to the defense forces.

Chief advantages of the system are its wide coverage, reaching many points simultaneously, its invulnerability, its contact with moving units.

The communication service will be particularly helpful in maintaining a complete picture of the hospital situation in the event that telephones are put out of order in an emergency. Ambulances can be loaded and dispatched quickly, and mobile medical teams sent from place to place without returning to their bases.

Hospital News

Dental Hygienists Needed for Army Dispensaries

TO SUPPLY the Army with needed dental hygienists, the U.S. Civil Service Commission has eliminated the experience requirement for such personnel. Many hygienists are in demand for Army hospitals and dispensaries throughout the country, particularly in the West and Southwest.

Dental hygienists are under Federal civil service regulations and are stationed only within the United States. They receive $1,970 a year entrance salary including overtime pay. The work week of forty-eight hours includes eight hours of overtime.

Completion of a course in a recognized school of oral hygiene and registration as dental or oral hygienist is all that is necessary to qualify for the positions. There are no age limits; no written tests. Standard application forms must be filed with the United States Civil Service Commission, Washington, D.C.

Persons studying oral hygiene may also file, receive provisional appointments, and enter on duty after completion of their courses and registration.

Persons who are willing to work in any part of the country have the greatest chance of receiving appointments within a short time. Applicants who desire information about living conditions, etc., in areas where Army hospitals and dispensaries are located, should, upon receiving offer of appointment, contact the appointment officer for such information. It is possible that vacancies will occur in the Public Health Service and the Veterans' Administration.

Persons already being utilized to their fullest capacity in war work should not apply. Federal appointments are made in accordance with War Manpower Commission policies and employment stabilization plans. Persons selected for appointment may be required to secure statements of availability, but these need not be secured until offer of appointment is received.

Full information and application forms may be obtained at first- and second-class post offices, at Civil Service regional offices, and at the U.S. Civil Service Commission in Washington, D.C.

New Ambulance Attendants Highly Satisfactory

MEDICAL authorities of the municipal and privately owned hospitals in New York City have revealed that the replacement of interns by trained attendants on hospital ambulances has worked out exceedingly well in eighteen months of operation.

Dr. Edward M. Bernecker, Commissioner of the Department of Hospitals, said that ambulance calls to all hospitals had been reduced by 59 per cent as a result of the new arrangement, the doctor shortage in many institutions had been appreciably eased, and many abuses had been eliminated. Bernard McDermott, president of the Greater New York Hospital Association and superintendent of the Long Island College Hospital, said that the new system was highly satisfactory and was giving adequate service to the public, while at the same time helping the hospitals out of a critical situation.

In 1941, the year before the interns were taken off the city and privately operated hospitals, the ambulances answered 503,646 calls in the city.

On February 15, 1942, the interns were replaced by attendants in municipal hospitals and two weeks later in private institutions. The calls fell to 359,718 and during the first six months of 1943 they went down to 147,009, or an estimated 294,018 for the year.

Dr. Bernecker explained the result by pointing out that a certain part of the public looked upon the ambulance service as a sort of mobile medical service, called upon it simply to obtain treatment by a physician, and, in more than half the cases, summoned ambulances when it was not necessary. Now that it is known that under ordinary conditions physicians will not arrive with the ambulance, these abuses are being eliminated.

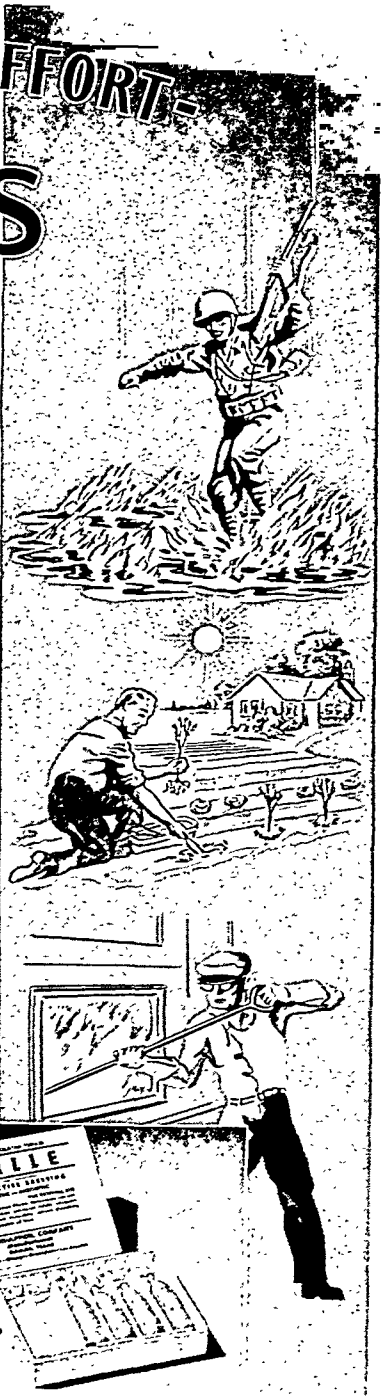
The new system has been in effect in 12 city hospitals and 36 private hospitals which provide ambulance service. Under ordinary circumstances the city hospitals used 60 full-time interns a year for this ambulance service, while the 36 private hospitals affected had to have 75 to 80 interns always available.

The municipal hospitals now have 136 trained attendants for the ambulance service in place of the interns, while the private hospitals have 145 to 150 such attendants. All attendants must have intensive courses in first aid and must possess Red Cross certificates.

Because of the acute manpower shortage, women are being called upon more and more to do this work in the municipal hospitals, and now 71 of the 136 attendants trained for the city hospital ambulances are women. They come principally from general hospital personnel.

Dr. Bernecker explained that the new system does not mean that emergency medical care at the scene of a serious accident is not still available.*

Student Nurses to Join Cadet Nurse Corps



MOST of the 100,000 student nurses of the country will enlist in the new United States Cadet Nurse Corps, according to Miss Lucille Petry, director of the Corps, which will be administered by Dr. Thomas Parran, Surgeon General of the U.S. Public Health Service.

For the past two years Miss Petry has been in

HAMPERING THE WAR EFFORT—

BURNS

THE increasing prevalence of burns among fighting men, industrial workers, even civilians, constitutes a major war hazard.

Whether the burn is due to fire, oil, or the effects of "Old Sol," effective first aid and local treatment is provided in

FOILLE

Foille provides quick relief from pain and encourages the healing process.

NOTE Foille can be applied immediately without debridement to a burned surface—it serves also as a valuable detergent for oil-stained burns.

Foille is now extensively used in military, industrial and hospital practices in the local treatment of 1st, 2nd and 3rd degree burns, wounds and indolent ulcers.

Available in

2-oz., pints, quarts, gallons
5-gallon bottles.

Distributed through Mine Safety Appliances Co., Surgical Supply Houses, Wholesale Druggists and Pharmacists.

CARBISULPHOIL COMPANY

3118 SWISS AVENUE, DALLAS, TEXAS, U. S. A. • CHICAGO • NEW YORK • LOS ANGELES • BIRMINGHAM

[Continued from page 1452]

charge of the Public Health Service's program. She is the first woman administrator in the U.S. Public Health Service. She recently was appointed dean of nurses of Cornell University, but has received a year's leave of absence in order to give her time to organizing the new nurses' training program.

Miss Petry is a graduate of Johns Hopkins University and of the Teachers College, New York. For ten years she was associate professor of nursing at the University of Minnesota.

"No possible prospect can be overlooked if we are to meet the heavy demand of the emergency," Miss Petry said. "The Army and Navy need 2,500 nurses a month. The increased hospital enrollment and the assignment of cadet nurses to Army hospitals will release graduate nurses immediately, although the full effect of the new act will not be felt until next July."

A letter to the nursing schools contains full details of the regulations and provisions arrived at after consultation with the national advisory committee, appointed by Paul V. McNutt, Federal Security Administrator, and composed of representative members of the nursing and medical professions.

A cadet nurse may choose between civilian or military service, the letter makes clear. She must promise only that she will serve during the emergency, in exchange for the free tuition, fees, uniform and monthly stipend of from $15 to $20 that she will receive as a cadet nurse.

"The oath the cadet nurse will take requires no more from her than her original motive to render service as a nurse," Miss Petry amplified. "It is just a guarantee that she will work at the profession during the emergency."

In line with the recent Army ruling which no longer requires that an Army nurse be dropped upon marriage, a cadet nurse may be married or may marry without jeopardizing her position.

The letter emphasizes that the Federal subsidy of nurse training will in no way endeavor to standardize schools of nursing. Although three years' training will be compressed into two, the student will continue to meet the admission, scholastic, and graduation requirements of the particular school in which she is enrolled. The program will not alter the relationship between the school and the individual student in any way.

The cadet will wear the student nurse uniform of her own hospital while on duty in the hospital, but all cadets will be provided with a distinctive street uniform which will identify them as members of the corps.

Improvements

Construction of the $149,325 temporary addition to Ellis Hospital in Schenectady will be commenced as soon as the War Department Production Board has granted necessary priorities, according to John M. Gallagher, director of Region One of the Federal Works Agency.

The structure is being built by Lanham Act funds allocated several months ago, and all plans and specifications have been approved. The new building will include wards with 90 beds and service facilities and quarters for interns which will release space for an additional 22 beds in the regular hospital building.*

• • •

Work was started in Canandaigua recently on a $442,000 addition to the Veterans Hospital, which will provide accommodations for 160 more patients at the neuropsychiatric facility.

Constructed of brick, the new building will be of wing design, with basement, two floors, and attic. The contract calls for completion within four hundred days, and approximately 100 men will be employed on the job.*

• • •

Ossining's Hospital of the future, planned in the light of anticipated needs, will be given concrete form under a long-range expansion and improvement program launched by the executive committee of the Ossining Hospital Board of Trustees.

Meeting June 15, the committee decided to engage Charles F. Neergaard, noted hospital consultant, to conduct a survey at the Ossining Hospital, mapping out plans which, when put into effect, would make the hospital the kind of institution needed in the community.*

A $50,000 to $70,000 hospital has been proposed to serve the mining towns of Fine and Clifton, and a campaign to enlist public support for the project is soon to be launched.

Committees to canvass sentiment and to collect funds for financing the undertaking have been appointed in the villages of Star Lake, Newton Falls, Oswegatchie, Fine, Cranberry Lake, and Wanakena, it was disclosed.

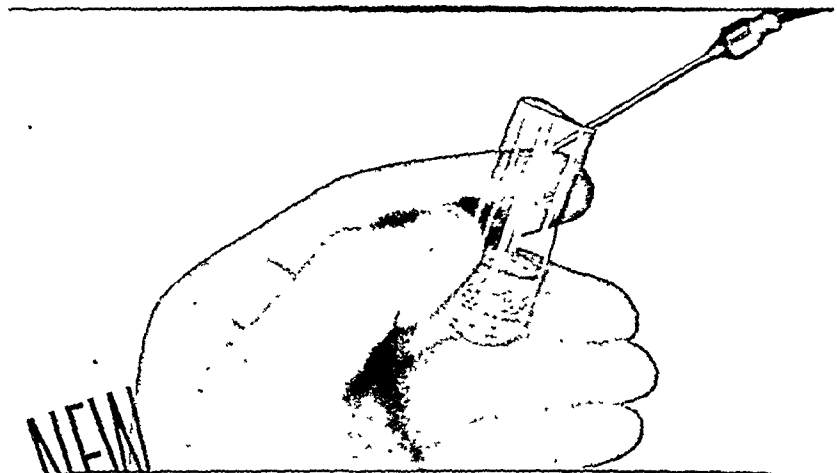
Sponsors of the proposal said that no site had yet been selected but that the hospital, if built, would probably be at a central point in order to provide for the needs of the two townships.*

• • •

A former basement dining room at Bellevue Hospital has just been converted into a 74-bed emergency hospital for use in an air raid.

The emergency unit, a complete hospital in itself, stands ready for instant action. Its operating room is completely equipped, right down to battery-powered lights which will throw their light where the surgeon needs it even if the central power system should be bombed out. Beds, in a large ward, are kept fresh with clean linen.

The hospital-within-a-hospital is twenty feet below the surface. Where its walls reach above ground, they are of brick and concrete and 3 feet thick. Windows have been blacked out by 3-foot thick brick "blisters," with only small square openings for light and air.*



• • •

Dr. H. F. Ettinger, who formerly maintained offices and a general hospital in Redwood, recently purchased the Scott Sargent house in Theresa and remodeled and redecorated the building into a modern hospital.

The institution has been named the North

NEW

ANTISYPHILITIC PREPARATION— YIELDS FRESH ARSENOXIDE SOLUTION

It is well known that arsenoxide is the effective end-product of arsphenamine compounds. Extensive clinical experience indicates that arsenoxide possesses a relatively constant parasiticidal value and that reactions following its use are less severe than with the arsphenamines.

Phenarsine hydrochloride—Winthrop  has within its molecule the nucleus for making arsenoxide.  With each dose there is incorporated an accurately adjusted amount of anhydrous sodium carbonate, sodium chloride and sugar. The addition of 10 cc. of distilled water instantly yields arsenoxide in isotonic solution (CO_2 escaping in gaseous form). Thus, the physician is assured that *each time in each case* the active antiluetic which he injects is fresh.

All forms of syphilis—primary, secondary, tertiary, congenital—are treated with Phenarsine hydrochloride—Winthrop.

Booklet containing essential details sent to physicians on request.

How Supplied: Ampuls of 0.045 Gm. and 0.068 Gm., boxes of 10. Ampuls of 0.045 Gm. and 0.068 Gm., boxes of 10 ampuls with 10 ampuls of sterile distilled water (10 cc.). Ampuls of 0.45 Gm. and 0.68 Gm., boxes of 10.

PHENARSINE HYDROCHLORIDE WINTHROP

[Continued from page 1454]

Country General Hospital and was officially opened to the public on Saturday, June 5.

Every floor has a minimum of two exits to be used in case of fire. The hospital has a full capacity of 25 beds, is entirely modern, and equipped for major surgery.

There will be two registered nurses on duty at all times. Miss Dorothy Abrahams, former superintendent of Mt. Eden Hospital, New York City, and Miss Dorothy Adamic, former operating room supervisor at the same hospital, will be in charge.*

. . .

Construction was begun in June on the new addition to Margaretville Hospital in Margaretville. The addition, a two and one-half story building, will raise the present bed capacity from 12 to 25 single rooms, with a top capacity, in case of emergency, of 50 beds. The addition is being erected at a cost of $40,000 and will include a completely new operating room and delivery room, together with additional surgical and obstetric beds. Two new nurseries are also included in the plan.

. . .

In Watertown, construction of the new two-story School of Nursing of the Mercy Hospital, to be known as McAuley Hall, is progressing rapidly. Excavation and foundation work started last fall, but work on the superstructure did not begin until April. Most of the first floor walls are already built. About 40 men are engaged in the construction of the building.*

At the Helm

Chester H. Lang was re-elected president of the Ellis Hospital Association of the City of Schenectady at the annual meeting of the association at the hospital on June 21. Also renamed were Robert H. White, vice-president; Arthur S. Golden, vice-president; Allen P. Marshall, treasurer and assistant secretary; and W. Howard Wright, secretary.

Re-elected directors for terms of three years were Jesse M. Howell, Austin Liecty, W. L. Lentz, Edward A. Mahoney, Roy C. Muir, and James W. Yelverton. Renamed assistant managers for one-year terms were Ellis F. Auer and Ernest E. Johnson.*

. . .

Miss Frances E. Dalton, new superintendent of the Leonard Hospital in Troy, completed eighteen years of service with that institution on June 21.

Miss Dalton became affiliated with the hospital as night superintendent, a post which she filled until her appointment as superintendent on February 22 of this year.

Foremost among the changes that Miss Dalton has instituted is a complete new dining room for employees. The new rest room for the nurses' aides is modern and complete in every detail. In addition, a rest and recreation room has been equipped for the kitchen employees, where they may spend their off time in relaxing or reading. Facilities have been placed there for card and checker games for the workers.

Miss Dalton has also brought about the arrangement of new storerooms.*

. . .

Alfred L. Golden, author and playwright and former public relations director of the Hospital Service Association of Pittsburgh, has been made director of public relations of the Associated Hospital Service of New York, it was announced recently by Louis H. Pink, president of the organization. William G. O'Brien, of White Plains, formerly with the War Production Board, has been made director of sales, a new division under the supervision of Frank Van Dyk, vice-president in charge of enrollment.*

. . .

Beginning July 1, 15 Poughkeepsie-area physicians and surgeons took the place of interns at Vassar Brothers Hospital, inasmuch as no interns will be available to the institution from July to January 1, 1944.

Dr. Scott Lord Smith, chief of staff of the hospital, said that the acute shortage of physicians in the country, brought on by the needs of the armed forces, "will make its first real appearance in Dutchess County because of the loss of the services of the interns at Vassar Hospital." The local hospital has had the service of five interns, and, under a limited allotment, two interns will be made available to the institution on January 1, 1944.

Meantime, the 15 physicians and surgeons of the Poughkeepsie area who have volunteered their services will serve a 24-hour day about twice a month at the hospital.

"In order to meet this condition at Vassar Brothers Hospital," said Dr. Smith, "the attending and assistant attending physicians and surgeons at the hospital have volunteered to give one full day's time at intervals of about two weeks, which they will spend entirely at the hospital, from noon of one day to noon of the next day, to carry on the routine work of the interns."

These doctors will be known as Officers of the Day. Any of their patients, who feel that they must see them, can find them at the hospital on the days when they are scheduled there.

Dr. Frederick M. Hedgecock, of Poughkeepsie, received the first assignment as Officer of the Day at the hospital.

The other physicians and surgeons who have volunteered to serve during two full days of the month are:

Drs. Clifford A. Crispell, Albert A. Rosenberg, Emil A. Stoller, William E. Garlick, of Wappingers Falls; William H. Meyer, Gilbert MacKenzie, of Pleasant Valley; John M. Jacobus, Aaron Sobel, Howard Townsend, John H. Dingman, Donald Malven, Archibald W. Thomson, Scott Lord Smith, and Joseph L. Cummings.*

For Summer Sinusitis use

SULMEFRIN

(Squibb Stabilized Aqueous Solution Sulfathiazole Sodium with Desoxyephedrine Hydrochloride)

SWIMMING and diving account for a high incidence of sinusitis during the summer months. This year you can provide your patients with prompt, effective relief by prescribing Sulmefrin.

Sulmefrin*—a new combination of sodium sulfathiazole (2.5%)—and *dl*-desoxyephedrine hydrochloride (.125%) is indicated for the intranasal treatment of sinusitis; relief of nasal congestion, and infections secondary to the common cold. It may be administered by spray or drops, 5 to 10 minims into each nostril, 2 to 4 times daily; or by tamponage, 20 minims on each pack, applied for 15 to 30 minutes once a day.

Sulmefrin Provides These Advantages

Affords quick relief of nasal congestion—facilitating drainage and ventilation • *Mildly alkaline* (pH 8.9 ± 0.3) helping to dissolve mucous and mucopurulent secretions. • *Practically non-irritating*—Producing effective shrinkage of swollen tissues without subsequent edema, sneezing, tachycardia or nervousness. • *Remarkably stable*—As demonstrated by exposure to direct sunlight, air, oxygen and boiling.

Sulmefrin is available in 1-ounce and 1-pint bottles. Caution should be observed in administering this preparation to patients who have exhibited sensitivity to sulfonamides.

* "Sulmefrin" (Reg. U. S. Pat. Off.) is a trade mark of E. R. Squibb & Sons

method was reported last fall, have been promoted by the U.S. Public Health Service.

Dr. Hollingsworth, who has been at the Island Hospital since 1937, was raised in rank from senior surgeon to medical director—the equivalent of a colonelcy in the Army or a captaincy in the Navy.

The two doctors whose discovery of the easy childbirth method was described in the *Journal of the American Medical Association* and in newspaper and magazine interviews are Dr. Robert A. Hingson and Dr. Waldo B. Edwards.

Both have been promoted from passed assistant surgeon to surgeon—a rank equivalent to a majority in the Army or a lieutenant-commandership in the Navy.

Other promotions at Marine Hospital are:

Dr. Donald J. Galagan, from passed assistant dental surgeon to dental surgeon; Dr. Charles R. Mallary, from passed assistant surgeon to surgeon; Dr. Donald W. Patrick, from passed assistant surgeon to surgeon; Dr. Raymond S. Roy, from passed assistant surgeon to surgeon; Dr. James L. Southworth, from assistant surgeon to passed assistant surgeon (the latter the equivalent of a captain in the Army or a lieutenant in the Navy); and Thomas C. Armstrong, from passed assistant pharmacist to pharmacist.*

• • •

The Surgeon General's Office recently came to the rescue of the Binghamton City Hospital to prevent that institution from operating without a resident physician.

At the appeal of Jerome F. Peck, superintendent, a year's deferment from Army medical service was granted for Dr. Lloyd D. Tuttle, who has been an intern for a year at the hospital, so that he can head the undermanned intern staff.

Mr. Peck said that Dr. Tuttle is a reserve officer. Five other City Hospital interns who also hold reserve commissions are due to be called into active service.

The hospital was assisted in retaining the resident physician through the Hospital Board of Procurement and Assignment Service of the Surgeon General's Office.*

• • •

The board of managers of Nathan Littauer Hospital, in Gloversville, has elected Samuel Rothschild president of the board for the coming year. Mr. Rothschild, who was vice-president of the board, succeeds the late A. C. Saunders, who served as president from 1926 until his death.

It was announced at the meeting that Lucius N. Littauer is preparing plans for the erection of either a wing or a new floor on the laboratory building, as a memorial to Mr. Saunders.

Another memorial to Mr. Saunders was announced by Jacob Zuckerwar, a member of the board, who plans to donate a modern electric bookkeeping machine.

The board elected John Naudin vice-president to succeed Mr. Rothschild. Miss Jennie Walker was named superintendent and executive manager of the hospital, and Miss Marjorie McComb was promoted from superintendent of nurses to assistant superintendent of the hospital.

The board announced that Miss Lillie Deimler has been engaged as superintendent of nurses to succeed Miss McComb. Miss Deimler is a graduate of the University of Pennsylvania, and is taking her master's degree at New York University. For the past ten years she has been instructor of nurses at the Wilkes-Barre, Pennsylvania, general hospital.*

• • •

Twenty-three Army officers, six of whom are from the State of New York, have been assigned to duty at Rhoads General Hospital, which is now under construction in Utica.

New York State physicians on the staff will include Lt. Col. Edward K. Reid, of Rome, executive officer of the hospital; Lt. Col. Arthur C. Roblin, of Syracuse, head of the dental service; Major Louis D. Dantzig, of New York City, specialist in dermatology; Capt. Myron L. Ogden, of Utica, of the dental corps; Capt. Louis A. Jones, formerly of Utica, post exchange officer; and Capt. John W. Calder, of Utica, Medical Administrative Corps.

The 116-building institution, which is to have facilities for 1,500 patients, will probably be opened some time in the middle of the summer, according to Col. A. J. Canning, commanding officer.

• • •

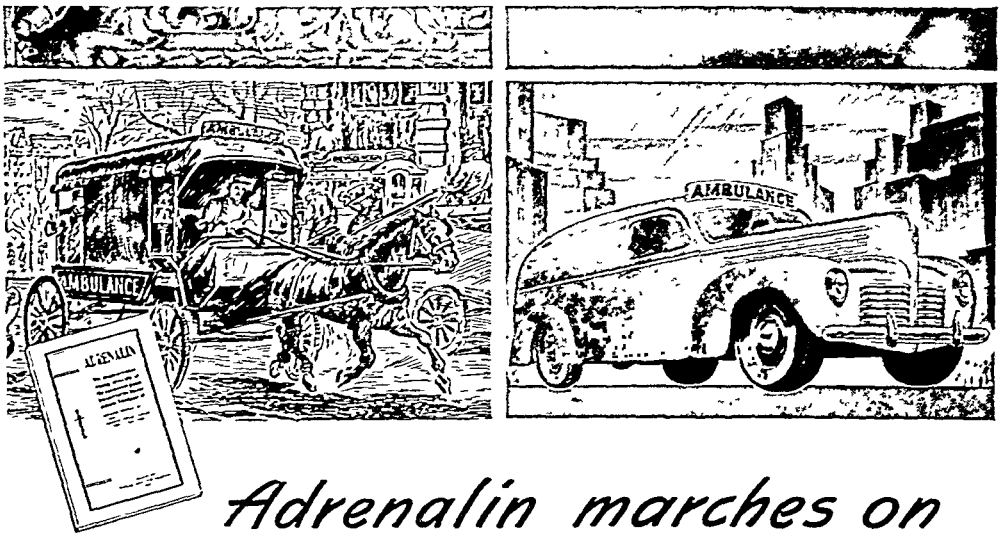
Dr. C. P. Rhoads, director of Memorial Hospital for the Treatment of Cancer and Allied Diseases in New York City, has been given leave of absence to become Chief of the Medical Division of the Chemical Warfare Service of the United States Army, with the rank of colonel, according to Harry Pelham Robbins, president of the hospital.

Mr. Robbins announced also the appointment of Dr. F. W. Stewart, pathologist of the hospital, as acting director, with Dr. Howard Taylor, Jr., attending surgeon of the gynecologic service, as his assistant.*

• • •

Dr. Jesse L. Bennett, a member of the staff of the Creedmoor State Hospital for more than ten years, has been named acting superintendent to succeed Dr. George W. Mills, who resigned after more than thirty-seven years in the state medical service.

Dr. Bennett came to Creedmoor March 15, 1932, and was promoted to the post of first assistant superintendent a year ago.*



Newsy Notes

In winding up the year's activities, reports were received from various committee chairmen of the New Rochelle Hospital Board of Governors at their meeting on June 21.

Mrs. Harold W. Herrick, president of the New Rochelle League for Service, presented the board with a check for $10,000 which represented receipts from the League's spring activities, the Hospitality Corner in the Hospital, and the Thrift Shop.

Mrs. Frank Hermes, chairman of the annual church bridge committee, presented a check for

Adrenalin marches on

"The therapeutic applications of adrenalin are already numerous and new uses for it are constantly being found out by different experimenters. Generally speaking, adrenalin, when locally applied, is the most powerful astringent and hemostatic known . . . and it is the strongest stimulant of the heart . . . it will unquestionably attain to a prominent place in the materia medica."

A Parke-Davis publication issued in 1902.

Today—four decades after isolation and crystallization of ADRENALIN* (epinephrine hydrochloride)—a great volume of literature attests to the high place it has attained in materia medica. Physicians know its amazing record as a circulatory stimulant, vasoconstrictor and hemostatic. ADRENALIN is the 20th Century's first great medical discovery. No trade-marked product has found wider acceptance; none enjoys a wider field of usefulness.

*TRADE-MARK REG. U. S. PAT. OFF.

Adrenalin

The active principle of the medullary portion of the suprarenal glands was isolated in crystalline form and its chemical structure determined in 1901 by Parke, Davis & Company

[Continued from page 1458]

$3,907, which represented returns from bridges and special donations from 20 churches in New Rochelle, Larchmont, and Pelham. This amount represents an increase of 25 per cent over last year's returns.

James T. Heenehan, chairman of the Membership Appeal, which is being held in observance of the hospital's fiftieth anniversary, announced a total of 507 new memberships for a total of $7,531.*

. . .

The annual June festival of St. Mary's Maternity Hospital and Children's Home, sponsored by the Circle of Mercy in Syracuse, was held on June 12 on the hospital grounds, the proceeds providing new equipment in the children's department.

. . .

Legacies of $21,351.31 have been paid to the board of trustees of Crouse-Irving Hospital and the Old People's Home department of the Hartford, Connecticut, Hospital, and one of $3,000 to the Syracuse Association of Workers for the Blind, under the will of Henry Howard Smith.*

. . .

Consolidation of the Robin's Nest, children's hospital in Tarrytown, and the Tarrytown Hospital has been unanimously agreed upon by the governing bodies of the two institutions and now awaits only favorable action by the members of the corporations before being consummated.

According to the plan of consolidation outlined in letters addressed to the members of the Tarrytown Hospital Association and of the Robin's Nest by Frederick P. King and Mrs. Henry K. Browning, respectively, the funds of the Robin's Nest will be used in the development of the new Tarrytown Hospital site on the former David Luke estate on Broadway at the White Plains Road, while the name of the Robin's Nest will be perpetuated by giving that name to the children's ward of the enlarged hospital.*

. . .

The "floating hospital" of St. John's Guild entered on its seventy-seventh season July 1, with almost 300 mothers and children on board for its first trip of the summer.

. . .

Reliance on volunteer workers is becoming increasingly necessary for many hospitals throughout the state. In an effort to offset the manpower shortage, Nassau Hospital in Mineola has offered to train men volunteers, as well as nurses' aides, for duties as orderlies and assistants. According to George L. Davis, superintendent, instruction given at Nassau Hospital does not obligate the volunteer to serve there, for graduates of the course will be accepted in any hospital in the county.

A nucleus of 7 men has already been formed for the Men's Volunteer Attendants, whose classes will begin early in August. Volunteers will wear white uniforms, with black, pin-stripe jackets supplied by the hospital.

In Niagara Falls both Memorial Hospital and Mt. St. Mary's Hospital have asked for men to fill hospital staff vacancies during the four-hour shifts between 8 A.M. and midnight.

Requests have also been renewed for nurses' aides.

. . .

Continuing the campaign launched in the recent city-wide CDVO recruitment drive, the Department of Hospitals recently began the distribution of 150,000 pamphlets for enrolling additional hospital volunteers and members of the Citizens Defense Nurse Corps of the Emergency Medical Service.

The pamphlets will be distributed through the borough CDVO offices, the United Hospital Fund, and the 1,600 Sector Warden Headquarters of the Air Warden Service.

The hospital volunteer pamphlet states that volunteers for many types of service are urgently needed "because thousands of doctors, nurses, and other hospital workers have gone to war," and because this trained personnel cannot now be replaced. The Citizens Defense Nurse Corps pamphlet seeks the enrollment of registered nurses for the Emergency Medical Service, set up to provide medical care for the civilian population in the event of enemy action. Citizens Defense Nurse Corps members will assist in caring for air raid casualties at the scene of an incident and in casualty stations and hospitals.

"Our hospitals are in dire need of additional volunteers," said Hospital Commissioner Edward M. Bernecker, in announcing distribution of the pamphlets. "We have a place in our hospitals for every type of volunteer service and sincerely hope many hundreds more men and women will enlist in this necessary work on the home front. Volunteer workers can relieve the professional staffs of much necessary clerical work and of other duties and, furthermore, these volunteers would be invaluable in any emergency that may come to our city because of enemy action."

. . .

The first women's ambulance unit of the Mission Militaire Française made its initial public appearance in new khaki uniforms on Bastille Day in New York City. Fifteen French women and one American compose the unit, named the Rochambeau, which is scheduled to leave soon to join the French Army with headquarters in North Africa. It was organized by Mme. Madeleine de Montgomery, director of the Section Féminine of the mission.*

. . .

The new twelve-story Lebanon Hospital, in the Bronx has been taken over by the Army for the Wacs.

L. Victor Weil, president of the institution, said that the hospital was the first institution taken over by the Army to be used exclusively for women.

The hospital, Mr. Weil stated, was proud to be in the position to turn over to the medical division of the Army "not only a charitable but a patriotic institution."

AN EXPLANATION

Question.—I would like to ask you a fair question. If a doctor is doctoring a doctor, does the doctor doing the doctoring, doctor the doctor the way the doctor being doctored wants to be doctored or does the doctor doctoring the doctor doctor the doctor the way he usually doctors?

Answer.—As I understand it, the doctor doctors the doctor the way he thinks the doctor should be doctored, but while the doctor doing the doctoring is doctoring the doctor, the doctor being doctored demands that the doctor doctor him the way he, the doctor who is being doctored demands. The doctor doing the doctoring and the doctor being doctored then get into an argument about the doctoring. This aggravates the doctor being doctored, and the doctoring done by the doctor doing the doctoring is of no avail. That is why doctors die younger than other people. I hope I make myself clear. —*E. V. Durling, in the San Francisco Examiner*

ANTI-CANCER—"N"

1. Primitive races eating freely of visceral organs as well as muscle meat, have very little cancer.

2. Civilized white men, limiting their flesh diet practically exclusively to muscle meat, have a high cancer incidence.

3. The cancer rate of primitive races increases as visceral meat is decreased in the diet.

4. Cancer is probably a dietary deficiency disease due to absence of some constituent of certain visceral organs. From the investigations of others it appears that this constituent is most abundant in brain and stomach tissue.

5. Therefore, to prevent cancer, one might conclude that brain or stomach tissue should be added to the diet.

6. The name "Vitamin N" is tentatively suggested for the cancer inhibiting factor.—*Ill. Med. J*

IN WHOOPING COUGH

ELIXIR BROMAURATE IS A UNIQUE REMEDY OF UNIQUE MERIT

Cuts short the period of the illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 or 4 hours.

GOLD PHARMACAL Co., New York

Woman's Auxiliary

To the Medical Society of the State of New York

THE National Convention of the Woman's Auxiliary to the American Medical Association was held in Chicago, June 6–9, with headquarters at the Drake Hotel. There were 171 members and guests registered.

New York State was represented by Mrs. Luther H. Kice, Mrs. H. F. Pohlmann, Mrs. Carlton F. Potter, Mrs. Carlton E. Wertz, and Mrs. J. Emerson Noll. Mrs. Noll served on the nominating committee. Mrs. Luther H. Kice was reappointed to the chairmanship of the Legislative Committee by the incoming President.

At luncheon on Monday, June 6, Dr. Frank P. Hammond, Chairman of the Advisory Council of the Illinois State Medical Society, spoke on the subject "Doctors' Ladies—Their Closest Allies."

Immediately after the luncheon, the opening session of the House of Delegates was called to order. The afternoon was devoted to reports of officers and committee chairmen. At the second session, reports of state presidents were received. All these reports showed a constant, healthy growth of the Auxiliary and much enthusiasm for the future. One new state auxiliary, Maryland, was organized during the year, with 22 members in one county unit.

This new auxiliary was represented by its organizing president, who reported progress in further organization in the state. A total of 42 states are now organized. Twenty-seven states were represented by reports read.

On Monday afternoon a tea was given, honoring the President and President-Elect. A luncheon in honor of the past national presidents of the Woman's Auxiliary was held on Tuesday, June 7, at which Brigadier General Fred Rankin, retiring president of the American Medical Association, and Dr. James E. Paullin, the new president, were guest speakers. Brief remarks were also made by Dr. Morris Fishbein, editor of the *Journal* of the A.M.A., and Dr. W. W. Bauer, chief of the Bureau of Education of the A.M.A.

At the session Tuesday afternoon, the following slate of officers was unanimously elected: president, Mrs. Eben E. Cary, of Wisconsin; president-elect, Mrs. David W. Thomas, of Pennsylvania; first vice-president, Mrs. Eustace A. Allen, of Georgia; second vice-president, Mrs. J. Howard Hornberger, of New Jersey; third vice-president, Mrs. F. G. Lindemulder, of California; fourth vice-president, Mrs. F. W. Mulsow, of Iowa; recording secretary, Mrs. David T. Berg, of Montana; treasurer, Mrs. H. F. Wahlquist, of Minnesota; directors (two years): Mrs. J. P. Simonds, of Illinois; Mrs. E. Hamer, of Arizona; and Mrs. W. W. King, of Colorado; and director (one year), Mrs. Frank N. Haggard, of Texas.

MRS. J. EMERSON NOLL

County News

Columbia. The last meeting for the year was held at the Nurses' Home of the Hudson City Hospital. The officers were installed for the coming year. The usual work for the Hospital followed the business meeting.

Nassau. Mrs. Byron D. St. John, of Port Washington, has been appointed convention chairman for the 1944 convention, to be held in New York City. The sixth annual Cancer Institute was held on May 12. Mrs. Luther H. Kice and Mrs. H. B. Ritchie were the guest speakers. The annual meeting and luncheon were held at Hotel Woodstock, New York City. Nassau County has had a series of outstanding educational programs this year.

AND ANOTHER THING

Anent the conservation of time and energies of hospital staffs, we have often wondered if flowers, which are so pleasant and agreeable in the daytime, suddenly become poisonous in a marasmic way with the advent of darkness.

If they do not, why is about an hour of the nurses' valuable time taken each evening in setting them all out to clutter up the corridors, and in moving them back into the rooms in the morning?

Are they supposed to "use up the oxygen" during the night when the patient sleeps? Cut flowers are dead, for all respiratory purposes, and the growing plants utilize light and carbon dioxide and give off oxygen in their growing process.

The reason for, and meaning of, this custom of moving all of the plants and flowers out of patients' rooms at night must be lost in antiquity, like the meaning of the buttons on a man's coat sleeve.
—*Rocky Mountain, M. J.*

"ANXIETY CHEMICAL" FOUND IN BLOOD

Chemists have found a mysterious "anxiety chemical" in the blood stream of persons under emotional stress, it was disclosed recently at the New York Academy of Medicine.

While the nature of the chemical still is unknown, four physicians at the New York Hospital reported that the secretion exuded in the blood of a person during an acute emotional experience modified the rhythmic contractions of a rabbit intestine.

They pointed out that the blood from normal subjects, those without emotional disturbance, showed no effect in the experiments, thus emphasizing that the changes in a body during an emotional strain were caused by the chemical in the blood stream.

The report was submitted by Drs. A. T. Hilhort, S. M. Small, E. J. Doty, and W. P. Bartels, of the Payne Whitney Psychiatric Clinic of the New York Hospital.

COT-TAR
PIX-LITHANTHRACIS 5%

- Therapeutically active in exudative and chronic eczema—particularly suitable in children's eczema.
- Forms a flexible non-peeling coat of tar.
- Can be removed with water or cleansing creams.
- Avoids staining of linen.
- Causes no untoward irritation.

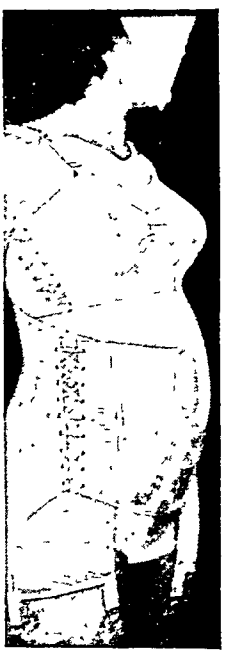
BILLIONS?

Money in circulation, just a few months back, amounted to approximately $15,000,000,000 (about $115 for every man, woman, and child in this country).

In order to appreciate the extent of this amount and its significance, one must realize the fact that it is three times the peak figure reached during the boom of the 20's and double the amount recorded in September, 1939, at the outbreak of the present war in Europe.

Greatly increased war industries and payrolls, and prevailing low savings bank interest have been contributing factors to a situation which must be regarded as a threat for further inflationary trends. In the past ten years, successive government spending of millions and billions for attempted rehabilitation from the depression, for defense and the war effort have been so common that the average person remains semi-indifferent, though somewhat hazy, regarding the magnitude of 15 billions of dollars and what it represents.



What is a billion dollars?

What do you think? Maurice Sherman, editor of *The Hartford Courant* (Conn.), tells the readers that if a person were to spend one dollar per minute it would take 1900 years to spend a billion dollars—or if he started in the year 700 B.C. with a billion dollars and spent a thousand dollars a day, there would still be a million dollars left on January 1, 2039 (96 years from now).

Multiply this by 15 and you get a picture of the money in circulation.

POSTPARTUM BACKACHE
often averted by prescribing a
SPENCER
Maternity Support
for wear during pregnancy

Orthopedists tell us that they are noting an increasing number of postpartum back cases particularly among primaparas.

Patient with 5 months' development wearing an Individually Designed Spencer Maternity and Breast Support. Usable after childbirth, too!

By wearing a Spence Support during pregnancy, designed especiall for her, the patient is protected against undue fatigue and back strain before and after childbirth

A light, flexible Spencer Maternity Suppor will be individually designed for your patient. I will provide support fo lower abdomen, with freedom at upper abdomen; improve posture relieve pressure; preven and relieve backache an nausea when not patho logical. Designed of non elastic material. *Guaranteed* never to lose its shape. Easily adjusted t increasing development.

Spencer Supports are neve sold in stores. For a Spence Specialist, look in telephon book under "Spencer Corsetiere" or write direct to us.

REVIEWED

Healthy Babies Are Happy Babies. By Josephine H. Kenyon, M.D. Third edition, completely revised. Duodecimo of 343 pages. Little, Brown & Co., 1943. Cloth, $1.50.

The theme of this book as given in the title is most appropriate. Any physician with experience in baby care will surely agree with the fundamental thought underlying the presentation. As a practical, up-to-date handbook on the care, health, feeding, and training of infants and young children this publication of Dr. Kenyon's has earned well-deserved recognition and popularity. It is an excellent guide for the mother, replete with information and sensible advice by an author whose opinions are authoritative and based on long experience.

JOSEPH C. REGAN

Manual of Veterinary Bacteriology. By Raymond A. Kelser, D.V.M., and Harry W. Schoening, V.M.D. Fourth edition. Octavo of 719 pages, illustrated. Baltimore, Williams & Wilkins Co., 1943. Cloth, $6.50.

The fourth edition of the book by General Kelser, chief of the Army veterinary division, was prepared by Dr. Harry W. Schoening. The volume is most appealing in its external appearance as well as in the arrangement of the subject-matter. The modest title does not do justice to the contents, which includes chapters on theories of infection and immunity, bacterial variation, fungi, protozoa, viruses, serology, and hematology. The part on systematic bacteriology is arranged according to the orders of bacteria following Bergey's *Manual*, with ample information on the pathogenicity and epidemiology of the various species. The book is unique in combining scientific thoroughness of presentation and up-to-date quotations from the literature with detailed descriptions of technical procedures.

S. BORNSTEIN

Outline of Psychiatric Case Study. A Practical Handbook. By Paul W. Preu, M.D. Second edition. Duodecimo of 279 pages. Paul B. Hoeber, Inc., 1943. Cloth, $2.75.

Three years have elapsed since the first edition of this practical handbook, and now we have an extensively enlarged and revised second edition.

The reviewer is pleased to note certain revisions which add to the significance and usefulness for history-taking of adults, such as giving the first place to the complaint problem and the present illness about which the other components of the history-taking revolve. The chief contribution of the second edition lies in the addition of an extensive outline of case study for use with the child and adolescent, although developmental problems of infancy and early childhood are also touched upon. The outline of behavioral examination for use with the child is particularly commendable.

This book, which is a splendid example of the genetic-dynamic approach to a useful outline of psychiatric case study, is without a peer and will be widely read not only by the specialist in psychiatry, but also by medical students, physicians, psychologists, sociologists, and social service workers.

The publishers are to be complimented of its splendid format, easily readable type, and use of nonglaze paper.

FREDERICK L. PATRY

Medical Clinics of North America. Vol. 27, No. 1, January, 1943. (Chicago Number.) Philadelphia, W. B. Saunders Co., 1943. Published bimonthly (six numbers a year). Cloth, $16 net; paper, $12 net.

The first half of this number of the *Medical Clinics of North America* is devoted to gynecologic disorders that can be treated without hospitalization.

Nine different subjects are discussed by prominent Chicago gynecologists. The indications and technic of office procedures such as electrocauterization and electrocoagulation of the cervix, tubal insufflation, and the use of the pessary are described in detail. The endocrine problem in gynecologic practice is also included in this symposium.

The second half of the issue is devoted to medical subjects and includes articles on heart failure, digitalis, duodenal ulcer, renal disease, and leukemia.

Excellence in War Production

FOR developing and producing Sterile Shaker Packages of Crystalline Sulfanilamide especially designed to meet military needs, for supplying Mercurochrome and other drugs, diagnostic solutions and testing equipment required by the Armed Forces, and for completing deliveries ahead of contract schedule—these are the reasons for the Army-Navy "E" Award to our organization.

Until recently our total output of Sterile Shaker Packages of Crystalline Sulfanilamide was needed for military purposes. As a result of increased production, however, we can now supply these packages for civilian medical use. The package is available only by or on the prescription of a physician.

Supplied in cartons of one dozen Shaker Packages each containing 5 grams of Sterile Crystalline Sulfanilamide, 30-80 mesh.

ABSENTEEISM

According to the Office of War Information, war plants without systematic plans for reducing the causes of absenteeism have almost twice the rate of job absences as those which do have such programs. This fact was based on research among 18 war plants and interviews with their employees in various sections of the country, on talks with absentees themselves, and on information furnished by representatives of labor, management and community leaders.

Plants with systematic programs averaged an absence rate of 4.4% per month, while those with hit-or-miss methods ran almost double that rate An analysis of the records covering 1,800 workers (100 in each plant surveyed) showed:

1. Married women are absent most. Next come single men, then single women. Married men are absent least.

2. Employees of three months to two years service were most frequently absent. Next came those with less than three months service. Least absent were the old hands with more than two years experience.

3. New residents of the community are more often absent from the job than regular residents

4 Workers who object to plant health or safety conditions, or lunch arrangements, or promotional policy, are more frequently absent than satisfied workers

Suggestions made by the workers themselves for cutting down absenteeism, were:

1. Rearrangement of hours of work and not granting overtime pay for the week in which the worker is absent.

2. Improvement of plant conditions, community conditions, wages and productive efficiency.

3. Educate employees, reward regular attendance, and discharge the absentees and put them in the Army.

The typical proposals for rearrangement of hours of work showed the workers concerned with reducing long hours, or concentrating work so they will have afternoons or days to themselves Some were "Give Saturday afternoons off." "Let everyone take a day off a month to take care of personal work." "Permit one shopping day a month." "Give workers a vacation." "Give five and a half days a week and work longer each day."

Many complaints seem to be the difficulty of getting decent food in or near the plant.

THE MAPLES INC., OCEANSIDE, L.I.

A sanitarium especially for invalids, convalescents, chronic patients, post-operative, special diets, and body building. Six acres of landscaped lawns. Five buildings (two devoted exclusively to private rooms). Resident Physician. Rates $18 to $45 Weekly

"DOCTOR JONES" SAYS—

That old expression about getting "in a rut"—I s'pose there's an awful lot of folks that've grown up since the horse and buggy days that it don't mean much to 'em—that expression don't. All their roading's been in an automobile on hard roads. But I can remember back when, in the country, it was all dirt roads. Most everybody drove in the same track and along in the spring they'd get soft—the roads would and then they'd freeze and you'd have ruts five or six inches deep. If you had to pass somebody it'd be all your life was worth to get out of 'em.

It reminds me of that story about the farmer that his wife'd gone off her head. He said he couldn't understand how anything could've happened to her mind; she hadn't been off'n the farm in three years.

But getting "in a rut"—the way we use the expression it means getting in the habit of doing the same things over and over in just the same way day after day.

The old saying "nature abhors change"—that goes for human nature, too. A lot of folks, when they get in a rut, they feel sort of fearful about getting out of it and doing something different—like we used to wonder if the old buggy was going to tip over if we got out on the side. We didn't have any choice though. We couldn't all stay in the same ruts and pass each other, so we had to take a chance. And we usually got by all right. Yes, there's a lot of folks—it makes 'em nervous just to think about doing something different than they've been accustomed to—or doing it a different way. I suppose that's the main reason why there's usually opposition to innovations.

But variety, they say, it's "the spice of life." A spice—that's supposed to add flavor and give you an appetite and so on. And that's the way it seems to work. The fellow that stays in the rut can only go where the rut takes him and just following somebody else's wheeltracks ain't very inspiring. He not only loses his interest but he's liable to lose his nerve at the same time.

The fellow that refuses to be bound by ruts—he may use 'em when it serves his purpose but he ain't afraid to pull out and make his own track—that's initiative. Somebody said we ought to do something every day that we don't want to do. Anyway, when we're confronted with jobs we're fearful of, it's a challenge. Going ahead in spite of our fears—it's a lot easier next time. And these young folks—it may make all the difference between success and failure. "Anything to do with health?" Well, mental hygiene is health, ain't it?—*Paul B. Brooks, M.D., in Health News*

DOUBLE PURPOSE

"Please, Mister, give me another box of those pills which I got for my mother yesterday."

"I sure will, but did your mother say she liked them?"

"No, sir; but they just fit my airgun."

PRECAUTION

A logger who was, alcoholically speaking, somewhat oversubscribed, was making his way homeward through a dense patch of brush. Suddenly he heard a rattle at his feet, and beheld a rattlesnake coiled and ready to strike. The logger drew himself up with dignified solemnity and eyed the reptile with lofty contempt.

"Go ahead an' strike," he said, scornfully. "Never will ye find me better prepared."

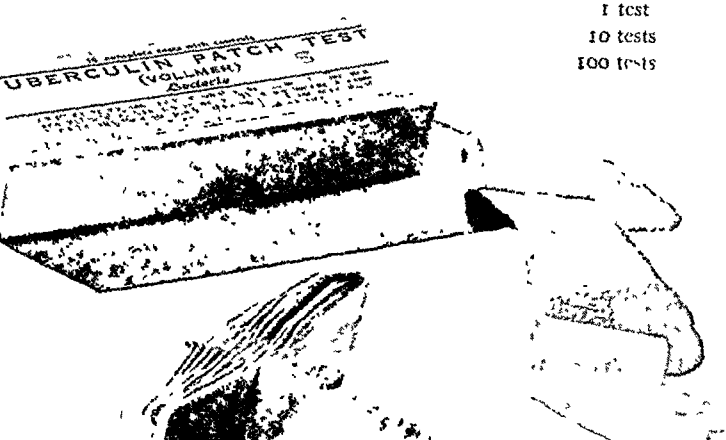
TUBERCULIN PATCH TEST

[VOLLMER]

Lederle

WITH THE THREAT of tuberculosis increasing in wartime, it is important to have available a simple, easy case-finding procedure.



Tuberculin Patch Test (Vollmer) was introduced by *Lederle* in 1937. Since then the curve of demand for this diagnostic agent has shown a steady rise, and its use in public screening campaigns has become widespread.

The Patch Test has achieved recognition because of its—

- SIMPLICITY OF APPLICATION;
- RELIABILITY;
- READY ACCEPTANCE BY BOTH CHILDREN AND ADULTS.

Keep a supply in your office—use it frequently—you will be surprised at the number of suspects you uncover. Send for samples and literature

TO BRING an effective analgesic into prolonged and immediate contact with the raw and painful throat accompanying pharyngitis and tonsillitis or following tonsillectomy, Dillard's Aspergum provides, in each tablet, 3½ grains of acetylsalicylic acid in a pleasantly flavored chewing gum base

Chewing Dillard's Aspergum, the patient releases a soothing flow of saliva laden with acetylsalicylic acid which reaches points often inaccessible to gargles or irrigations. In addition, the gentle muscular exercise helps relieve local spasticity. Because the patient is more comfortable, an adequate diet is resumed and maintained earlier, thus helping to reduce the convalescent period.

THE DIRECT ROUTE TO TONSILLAR REGION ANALGESIA

Dillard's Aspergum

A PARTICULARLY pleasant and convenient method to prescribe acetylsalicylic acid for children, who frequently cannot or will not gargle.

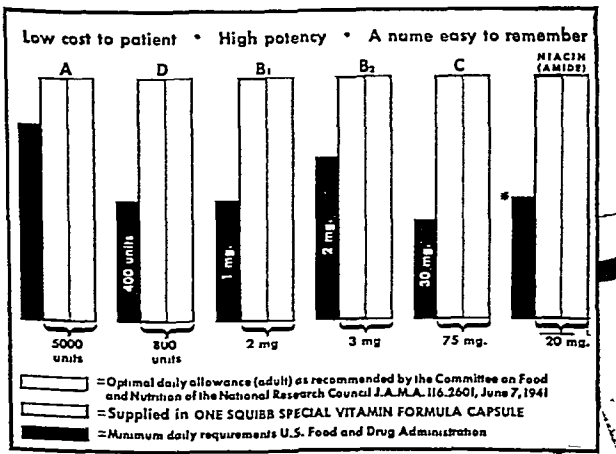
Two Important Forward Steps in Vitamin Therapy

1

For Severe Deficiencies of the water-soluble vitamins

Make this formula available to all physicians



SPIES,[1] JOLLIFFE AND SMITH[2] report that in treating patients with deficiency disease they supply the water-soluble vitamins routinely by the use of a "basic formula." To quote Spies[3]—"It is better to prescribe too much than too little, too soon rather than too late. . . . In treating the clinical syndromes of beriberi, pellagra, riboflavin deficiency and scurvy, we use a formula containing 10 mg. thiamine, 50 mg. niacin, 5 mg. riboflavin and 75 mg. ascorbic acid. If the symptoms of one deficiency predominate we add to the basic formula more of the vitamin specific for the predominating deficiency."

[1] Spies, T. D. *M. Clin. North America* 27 273, March 1943
[2] Jolliffe, N., and Smith, James J. *M. Clin. North America* 27.567, March 1943.
[3] Spies, T. D. *J. A. M. A.* 122 497, June 19, 1943

POINT by POINT MANDELAMINE

meets the test of an ideal* URINARY ANTISEPTIC

✔ CHEMICAL STABILITY

Mandelamine is chemically stable.

✔ EXCRETION OF SUBSTANCE UNCHANGED BY THE KIDNEYS

Mandelamine is excreted unchanged by the kidneys, thereby assuring sufficient concentration to exert antiseptic action.

✔ FREEDOM FROM TOXICITY IN THERAPEUTIC DOSES

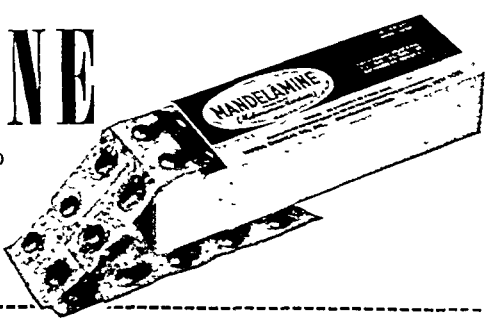
The resultant smaller dosage of mandelic acid and methenamine in Mandelamine virtually eliminates the by-effects which are common when either one of these components is used individually.

✔ FREEDOM FROM IRRITATION TO URINARY TRACT MUCOSA

Mandelamine is well tolerated . . . both systemically and locally.

✔ BACTERICIDAL ACTION

The rapidly effective bactericidal action of Mandelamine has been confirmed by more than two years of controlled clinical investigation, and an extended period of prescription use.



In addition to these important advantages, Mandelamine offers convenience of administration through elimination of the need for routine urinary pH control, accessory acidification, adjustment of fluid intake, and dietary regulation.

**As stipulated by Wesson, M. L.: West. J. Surg., Dec. 1941.*

MANDELAMINE

Reg. U. S. Pat. Off. (Methenamine Mandelate)

Degalol

THE ORIGINAL DEOXYCHOLIC ACID

for fat digestion and the absorption of fat-soluble vitamins

Degalol represents deoxycholic acid, the bile acid which is chiefly responsible for emulsification of food fat and the formation of the water soluble choleic acid compounds.

Degalol is valuable in biliary fistula, assuring fat digestion even with diversion of bile to the outside.

Degalol enhances absorption of the fat-soluble vitamins A, D, E, and K. In complete biliary obstruction with poor or absent fat digestion, Degalol makes possible utilization of food fat, and insures absorption of orally administered vitamin K.

Degalol consists solely of chemically pure deoxycholic acid. It is supplied in boxes of 100 1½ gr. tablets.

Riedel - de Haen, Inc. NEW YORK, N Y.

There's Not Another Like It

ARSENOFERRATOSE ELIXIR holds a distinctive position among liquid preparations of hematinic elements—because its organic iron is easily assimilated, its metabolism stimulating arsenic is therapeutically effective in minimal doses, and its delectable vehicle is agreeably palatable.

ARSENOFERRATOSE offers optimal regeneration of hemoglobin without producing undesirable side-effects; the stomach tolerates it at once and in full therapeutic amounts—thus the necessity for graduated doses is obviated; easy and convenient administration, precise and reproduceable pharmacologic action, and economy consistent with the type of fabrication required for this product—collectively, these desirable attributes make Arsenoferratose *the iron preparation of choice!*

Indications: For the treatment of hypochromic and other secondary anemias . . . To cure iron deficiency disease . . . To build iron reserve . . . To hasten convalescence . . . To prevent insufficiency of iron in today's restricted diets . . . To counterbalance possible blood damage in sulfa-drug therapy.

Supply: Elixir Arsenoferratose, and Elixir Arsenoferratose with Copper, bottles of 8 fl. oz. Tablets, bottles of 75.

Note: 1 teaspoonful of the elixir supplies more than the daily minimum requirement of iron for the normal adult.

THESODATE *Brewer*

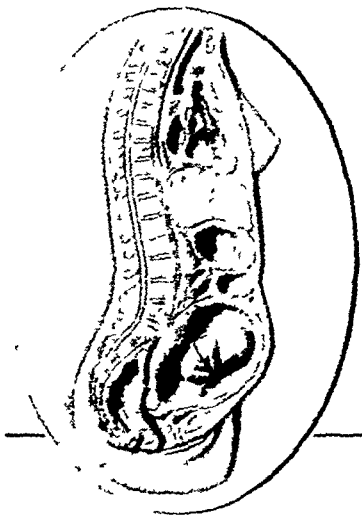
(the original enteric-coated tablet of Theobromine Sodium Acetate)

for

CLINICALLY EFFECTIVE
LOW TOXICITY
EFFECTIVELY ENTERIC COATED

CORONARY ARTERY DISEASE AND EDEMA

Medical authorities in journals and books have substantiated the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal Diseases. Actual clinical use has proven the usefulness of Thesodate *(Brewer)*.



The enteric coating of Thesodate tablets permits adequate dosage, so necessary for best results with xanthines, for as prolonged a period of time as necessary.

Supplied with or without Phenobarbital, also with Potassium Iodide and Phenobarbital, in potencies for controllable dosage.

Samples and literature on request.

ANATOMY OF PREGNANCY

This series of life-size sculptured models was executed for S. H. Camp & Company by Charlotte S. Holt

4 Lunar Months—Abdominal protrusion beginning. Uterus becomes abdominal organ. Fundus 4 cm. below umbilicus. Approximate time of quickening. Normal visceral relationship. No appreciable change in body mechanics.

7 Lunar Months—Beginning tension on recti. Uterine fundus 5.5 cm. above umbilicus. Cephalic presentation determined. Visceral displacement (upward and lateral). Lumbar and dorsal curves increased. Relaxation of sacro-iliac and pubic joints.

10 Lunar Months—Overdistension of recti and diastasis are obvious. Fetus and placenta fully developed. Head engaging (L.O.P.). Marked visceral displacement (upward and lateral). Marked lumbar lordosis "pride of pregnancy." Relaxation of pelvic joints.

No food (except breast milk) is more highly regarded than Similac for feeding the very young, small twins, prematures, or infants who have suffered a digestive upset. Similac is satisfactory in these special cases simply because it *resembles breast milk so closely,* and normal babies thrive on it for the same reason. This similarity to breast milk is definitely desirable — *from birth until weaning.*

ACCEPTED AMERICAN MEDICAL ASSN. Council on Foods

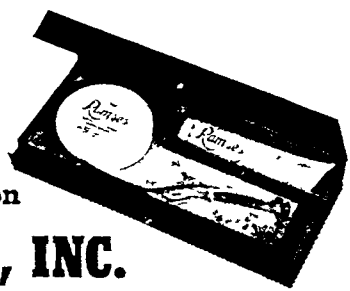
Perfectly MATCHED

THE items which make up the "Ramses"* Physicians Prescription Packet No. 501 are as perfectly matched as scientific development and controlled manufacture can make them.



Each "Ramses" Diaphragm is matched to a diaphragm Introducer of a corresponding size — and each is made to conform as closely as possible to the normal vaginal anatomy. Matching the accessories is the large-size tube of "Ramses" Vaginal Jelly, the pH of which is adjusted to 4, to match that of the vaginal tract.

Thus, perfect matching assures proper insertion, comfortable adjustment of the diaphragm to the vaginal walls and proper barrier action of the jelly.

The "Ramses" Physicians Packet No. 501 is available on your prescription, at recognized pharmacies.

ROUTINE URINE ANALYSIS SIMPLIFIED!

GALATEST MAKES URINARY SUGAR TESTING A MATTER OF SECONDS

WHETHER it's the occasional specimen in your office — or thousands in hospitals, war plants and induction centers—you can cut corners on *time* and *bother* with Galatest.

HOW TO MAKE A COMPLETE URINE SUGAR TEST IN 30 SECONDS

Step 1. A little Galatest powder. Step 2. One drop of urine. If sugar present—color reaction instantly.

AND THAT'S ALL THERE IS TO IT!

Diabetics welcome this dry reagent. At home or away from home, Galatest makes it easier for your patients to carry out their routine test for urine sugar. The handy, portable Galatest kit contains everything the patients require for a complete sugar test.

Send for descriptive literature.

BELBARB

AN *Excellent*

SEDATIVE and HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

QUALITY HAS NOT BEEN RATIONED

Statements made recently suggest that the war has brought great changes in the manufacture of shoes, that the government has confiscated all the best leather, and that all shoes today are "just alike" regardless of price.

Such statements have not only been misleading but damaging also to the manufacturers and dealers who have not been tempted by opportunities to use restrictions and priorities as excuses to produce and sell an inferior product with greater profits.

Pediforme, along with other reputable companies, has maintained the same pre-war quality in both materials and workmanship. Physicians can rely on that.

THIS is no time for a letdown. You, your patients, everyone finds it desirable to keep energy at its peak.

For there is a great drain upon energy these days. People are busier, working harder, crowding volunteer duties on top of hard days at a plant or office.

Physicians know better than anyone the need for replacing this used-up energy. They realize that weakened conditions invite attack from disease.

For replacing this energy the physician looks to the proper foods. In some there are already shortages. Most likely others will become short too. But there is one outstanding food that is plentiful, delicious and well able to supply a good part of the food-energy intake. This food is bread.

Bread is a rich source of carbohydrates. It supplies some proteins and some minerals. White bread is particularly well liked. And as made today, all white bread is enriched and provides extra amounts of thiamin, niacin and iron.

So where additional food-energy is indicated, we believe you will find bread an excellent prescription. It has been the foundation food for ages. And as supplied today it deserves this position more than ever.

Editorial

More Political Medicine

Proposed changes in the structure of American medicine by numbers of groups, associations, and corporations and by legislators were examined in a recent address[1] by Thomas A. McGoldrick, M.D., L.L.D., President of the Medical Society of the State of New York. "From the beginning of the World War we have heard from very many sources of the changes that would take place at its end. Numbers of groups—of associations and corporations, as well as of individuals—have with assumed prophetic vision proclaimed the many radical changes that they desire to take place. The report of the Twentieth Century Foundation lists nearly 140 such corporations, representing vast aggregations of wealth. It would seem as if very little now existing, or existing before the war—whether tried by time or experience, whether experimental or proved by usage—is worth saving. These workers are in full accord with the English economist who said that in a time of political revolution many drastic changes could be accomplished which in normal times would be impossible. A brand New World is sought—in fact is on the way. Now no person may ever find fault with *improving* existing conditions or practices; no one *should* find fault with the adjustment of methods for betterment. No one, however, no matter how well intentioned, should cast aside knowledge we now possess or sacrifice true progress which has been made. Long years ago, Erasmus said: 'The greatest folly of which a man is capable, is to sit down with pencil and paper to plan out a new social world.'"

Yet that very thing seems to be the plan and intent of many who would remold the free institutions of American medicine along the lines proposed by Senator Wagner and his colleagues in *S.1161; H.R.2861* as set forth in the August 1, 1943, issue of the JOURNAL.[2] One must believe the proponents of such a measure to sell the civil practice of medicine into slavery and bondage to be ignorant of or willfully blind to the continuing progress and remarkable results already attained by the profession. It is true, as Dr. McGoldrick points out, that "in some areas of this country, there are not enough doctors—not enough hospitals—not a sufficient number of laboratories, though not to such a degree as has been proclaimed by interested workers. In some sections of the country, everybody has not the facilities at hand and within his means to obtain every kind of specialist, every laboratory procedure, and every instrument of precision. Everybody has not the intelligence to desire or even accept the good medicine which is available. In regions of great ignorance the superstition, the voodoo, the charm, the universal medical mixture cure—all are preferred; in other sections, we have the hundred thousands of people choosing the 'isms,' the 'pathies,' and the faith cures; many more, able to select and pay for good preventive medical or dental prophylaxis or cure, prefer and choose other ways to use

[1] Utica, New York, July 13, 1943.

[2] New York State J. Med. 43: 1399 (Aug. 1) 1943.

their money. But everybody in the United States is sharing in the effects of ever advancing medical knowledge, which has given us the lowest mortality and morbidity rates of any country in the world with comparable population.

"A few years after the close of World War I, there was announced the discovery of insulin and its wonderful value to the million diabetics in this country. Following that came the results of the studies of anemia, the elements involved in the causation of the pernicious type, the use of liver extract with other remedies. Less than ten years ago chemotherapy presented us with the sulfonamide drug, with its successive preparations and their astonishing successes. The program in blood transfusion, the technical improvements, including the preparation and the preservation of plasma, and its uses, have been real advances—have been of immense life-saving benefits multiplied over in these terrible days. When through the fortunes of war, our allied nations lost the source of the greater part of their quinine—and when the need for antimalarial remedies was greatest for our soldiers in these foreign infested lands—medicine, with the great help of the pharmaceutic industries, synthesized the atabrin or quinabrin preparations that have so effectively substituted. The general reduction in infections, such as typhoid, diphtheria, tuberculosis, the treatment of venereal disease, the lowering of the death rate in maternity cases are but some illustrations of progress within these past twenty-five years. The value to the nation and to the individuals therein of the medical progress we have made is rarely mentioned—generally is not known. In Social Security plans the importance of the lives saved and the improvement of individual good health in preventing unemployment, in reducing absenteeism, in increasing income, in prolonging life in an earning capacity, in the shortened period for old-age pensions, is rarely properly appraised.

"The doctors were the earliest in the groups of real social workers. Besides being the possessors of ever increasing knowledge, they were the originators, the prompters, the inaugurators, and early directing guides of every hospital, every clinic in our land, and in their long-continued, unremunerated services have been the principal contributors and supporters of these institutions."

It is now proposed to sell these medical men who have initiated and accomplished all these things into a house of bondage, into a kind of economic and professional slavery to the Surgeon General of the United States Public Health Service.

If the people of the United States really want that to be done, it can be done, for better or worse. We believe, however, that if they are fully informed of the proposal and its probable consequences, the people will have in remembrance the accomplishments of a free, progressive, and liberal profession and will instruct their representatives to accord *S.1161; H.R.2861* the scant consideration they deserve.

The situation is serious. The medical profession is obligated to see to it that the people are fully informed of what is proposed and what such a proposal will mean to them.

The people will, in the final analysis, decide the issue.

Procurement of Physicians from New York State

In the June 15, 1943, issue of the JOURNAL, we asked of the A.M.A., what are the facts relating to the procurement of physicians in this State? Certain discrepancies seemed to exist in the figures at the disposal of the War Participation Committee of the Medical Society of the State of New York, and those published by the *J.A.M.A.*

Answering our editorial inquiry, the *J.A.M.A.*, says:

> "The official records of the Procurement and Assignment Service are derived from the Adjutant General of the U.S. Army, the Surgeon General of the U.S. Navy, and the Surgeon General of the United States Public Health Service. Careful tabulations are made from the official lists

after the individual physicians' names have been verified against known records. On January 31, 1943, there were 7,460 physicians on duty with the armed forces from the State of New York, while on March 31, 1943, there were 7,676 physicians on duty from that state. During the months of February and March, 1,035 were called to duty from the entire country. Each name credited by the Procurement and Assignment Service represents a physician who left a civilian practice and reported for duty with the armed forces. The discrepancy between the figures cited is doubtless due to the difference between the number of physicians who signified their willingness to serve their country in the armed services and the number actually commissioned and on duty."[1]

[1] J.A.M.A. 122: 749 (July 10) 1943.

Doubtless. However, the number commissioned was the basis for the statement that New York quotas had not been met. It is still a little difficult to see what a physician can do who has signified his willingness to serve his country in the armed services and whose commission is not forthcoming so that he may be ordered to active duty. It strikes us as not quite sporting that New York physicians in this predicament should be made whipping boys because of delays in processing, delays over which they could have no possible control. And that's that; let's get on with the war.

Abuse of Sulfonamides

On May 6, 1943, the Section on Dermatology and Syphilology at the Annual Meeting of the Medical Society of the State of New York passed the following resolution:

"WHEREAS, Repeated administration of sulfonamides either internally or locally may sensitize an individual to these drugs and thereby preclude their future use in serious diseases, such as pneumonia; therefore, be it

"*Resolved*, That the Section on Dermatology and Syphilology go on record as strongly disapproving the indiscriminate use of sulfonamide drugs in relatively harmless diseases of the skin which can be satisfactorily treated by equally efficient drugs; and be it further

"*Resolved*, That the Section condemn the use of prepared dressings containing sulfonamide drugs which are sold promiscuously to the laity."

Little can be added to the resolution, which so tersely, forcefully, and rightly condemns the indiscriminate use of sulfonamide products by physicians, manufacturers, and the public. It has not been generally appreciated, perhaps, that repeated administration of sulfonamides either locally or internally may sensitize an individual to these preparations. But as further clinical experience in their use and evidence of their abuse or misuse accumulate, a campaign of education directed to physicians, manufacturers of prepared dressings, and to the public seems indicated and should be carried out forthwith.

An additional warning may be added, according to Fisher, Accousti, and Thompson,[1] that the "rapidly growing medical use of sulfonamide powders, ointments, and solutions for topical application in superficial and deep wounds raises the question of the possibility of their becoming contaminated with pathogenic organisms not affected by the drugs." Apparently, serious contaminations do occur. Welch, Slocum, and Herrick[2] found contamination of sulfonamide dusting powders with tetanus, and the death of a patient in England has been reported[1] from tetanus following the postoperative use of powdered sulfapyridine in the abdomen.

In this issue, page 1499, David Bloom, M.D., in a paper entitled "The Danger of Cutaneous Reactions to Sulfonamides" reports two cases of bullous eruption following the use of sulfonamide and warns that in 1941 "more than 1,000,000 pounds of sulfanilamide and sulfathiazole were sold in this country, in addition to considerable amounts of sulfapyridine and sulfadiazine, and when one reflects that many thousands of lives are being saved by these drugs, the incidence of serious toxic reactions and even the several thousand fatalities known to

[1] J.A.M.A. 122: 855 (July 24) 1943.
[2] J.A.M.A. 120: 361–364 (Oct. 3) 1942.

have been produced by the drugs may seem negligible. But looking at absolute figures and considering the enormous number of individuals who have been and are unknowingly sensitized to these drugs and are potential victims of illness and death when at some future time the drug is given to them, one sees the necessity of preventing or reducing to a minimum the toxic and fatal reactions of the sulfonamides."

In the public interest this information should be widely and quickly disseminated.

Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York.

The Lucien Howe Prize of $100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of $100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the Prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1944, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

Committee on Prize Essays

THE DANGER OF CUTANEOUS REACTIONS TO SULFONAMIDES

Report of Two Cases of Bullous Eruption Following the Use of Sulfanilamide, One of Which Resembled Pemphigus Vulgaris

DAVID BLOOM, M.D., New York City

THE introduction of the sulfonamide drugs into the practice of medicine has unquestionably proved itself one of the most important milestones in the progress of therapy. Mortality has been reduced considerably in serious illnesses like meningitis, pneumonia, septic streptococcic infections, and wound infections on the battlefield, and morbidity has been shortened in many other diseases, such as gonorrhea, chancroid, and lymphogranuloma venereum.

But it is important to realize that these drugs, which are able to interfere so successfully with bacterial life and activity, are also potentially dangerous to the physiologic life of the cells of the human host. Thus, there have been observed toxic by-effects of these drugs which do not spare any organ of the body, affecting several of the organ systems simultaneously or disturbing them singly. The most dreaded of these effects are those that involve the hemopoietic system, leading to agranulocytosis or acute hemolytic anemia, and renal involvement, which may consist in parenchymatous damage or in obstruction of the urinary tract by crystals. The liver, the central and peripheral nervous system, the heart, the joints, and the skin may be affected. When these reactions are not closely watched or are ignored and the administration of the drug is continued, reactions which are mild may become severe and may even result in death. The exact incidence of fatalities produced by the sulfonamide drugs themselves is unknown. According to Long,[1] 200 such fatal cases have been reported. But this author rightly assumes that the actual incidence of mortality from this cause must be almost 5,000, for most cases are not reported.

In this paper I must confine myself to the by-effects of sulfonamides on the skin. I wish to emphasize here a fact that is not sufficiently known and considered by the nondermatologist—namely, that just as the hemopoietic system, the kidneys, and other organs may be affected both primarily and singly and may produce serious illness, so the cutaneous organ may also be affected alone, without necessarily being associated with a disturbance of any of the viscera or body systems. Interference with the physiologic functions of the skin may in itself lead to serious illness or death. Thus, in the patient reported by Weinstein and Domm[2] who died with exfoliative dermatitis after the ingestion of sulfanilamide, the autopsy did not reveal any satisfactory cause of death, and it had to be assumed that death was due to overwhelming toxemia produced by the drug. Also, the 3 cases of dermatitis found by Sutliff and his associates[3] among the 28 probable sulfonamide deaths in the records of the Pneumonia Control Division of New York City Department of Health, the Bureau of Vital Records and Statistics, and of the Chief Medical Examiner's Office, most probably died of the skin involvement. Two of these patients had generalized dermatitis which followed sulfathiazole therapy, and the third was one of exfoliative dermatitis which developed after the administration of sulfapyridine.

Like any drug reaction, these eruptions may be produced by different mechanisms (Sulzberger;[4] Greenwood[5]):

1. They may be primarily toxic effects, caused by some unknown weakness in the cells of the individual or in the detoxifying mechanism; in other cases they may be caused by the overwhelming effect of an excessive amount of the drug or its too prolonged administration. It has been observed that such a toxic eruption, after having cleared up, may not recur on readministration of smaller doses of the drug (Tedder[6]).

2. Another group of eruptions forming probably the majority of skin reactions to sulfonamides is of allergic nature, produced by acquired hypersensitivity of the skin, which may develop after ingestion even of small amounts of the drug. Characteristic of this type of reaction is the short interval between the readministration of the drug and the appearance of the eruption. It takes, according to Abramowitz[7] and others, at least seven days for the skin to become sensitized; therefore, the interval between the time of ingestion of the first dose of the drug and that of its readministration must be at least seven days in order that the allergic reaction manifest itself. When the drug administration is not interrupted but is continued during several weeks, the eruption may appear any time after seven days of drug therapy.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943

From the Department of Dermatology and Syphilology of the Sydenham Hospital, New York City.

3. The third type of mechanism is the so-called allergo-toxic, forming a combination of toxic and allergic effects. Not infrequently, when a reaction appears during a prolonged first course of the drug administration, it is difficult to distinguish between the two mechanisms and to evaluate the exact role played by the primary toxic and by the allergic mechanism (Spink[8]). For the toxic effect may be superimposed by gradual sensitization.

It has been observed that some of the early eruptions are precipitated by exposure to sun light (Newman and Sharlit[9]). According to Tedder,[6] this type of eruption is not necessarily associated with sensitivity to the drug. According to Combes and Canizares,[10] sunray sensitivity is not common following sulfanilamide administration.

Types of Sulfonamide Eruptions

The most frequent eruption observed, particularly during the first course of sulfonamide therapy, is the maculopapular, or morbilliform, type. The other types of eruption are scarlatiniform, erythema multiforme-like, urticarial, angioneurotic edema, erythema nodosum, purpuric, varioliform (Franks and Traub[11]), vesicular, pustular, which may be also follicular (Miller[12]), bullous (Omens and Robbins;[13] Bettley;[14] Epstein[15]), fixed bullous (Loveman and Simon[16]), exfoliative (Weinstein and Domm;[2] Sutliff and associates[3]), and pemphigus foliaceus-like (Wien and Lieberthal[17]).

The morbilliform and scarlatiniform eruptions may be mistaken for measles and scarlet fever. The erythema nodosum-like eruption has been mostly observed in the course of sulfathiazole therapy, but it has also been reported following sulfanilamide[16] and sulfadiazine (Costello[18]). Angioneurotic edema may seriously endanger the life of the patient when it involves the glottis. Such a case was reported by Schonberg,[19] and was also observed by the author, at the Skin and Cancer Unit, in a woman who had taken 1 Gm. of sulfathiazole. The patient had received, one month previously, 2 Gm. of sulfathiazole daily for four days, a course that was repeated later. This case was presented at the Manhattan Dermatological Society by Abramowitz.[20] In the case of Dennie[21] there was edema of the face, the upper extremities, and the tongue. A follicular pustular eruption of the extremities was observed by the author at the Skin and Cancer Unit in a man who had received, for the treatment of conjunctivitis, sulfathiazole simultaneously in the form of drops and ointment for local application, and tablets for oral use.

In association with the eruption on the skin there may be involvement of the mucous membranes of the mouth and of the conjunctivae and sclerae. Conjunctivitis and scleritis, which are limited to the exposed part of the bulbar conjunctiva and sclera, have been observed most frequently following sulfathiazole therapy and were reported among others by Haviland and Long[22] and by Volini, Levitt, and O'Neil.[23] In Costello's[18] series of cases treated with sulfathiazole, 5 per cent developed conjunctivitis. Costello describes the appearance of the eyes in this condition as bloodshot.

Several cases of bullous eruption following sulfanilamide and sulfapyridine therapy were reported. The patient of Loveman and Simon[16] developed, on readministration of sulfanilamide, bullae in the same areas of the skin and in the mouth as on the first administration of the drug. While these patients have recovered promptly after discontinuance of the medication, the patients reported by Wien and Lieberthal[17] did not recover. Nine days after the commencement of sulfanilamide therapy for otitis media and mastoiditis, this patient developed a morbilliform eruption, which was followed a few weeks later by a malodorous dermatitis exfoliativa and by bullae scattered over the body. He continued to be ill and to have fever and died six months after the appearance of the eruption. An autopsy revealed tuberculous tracheobronchial lymph nodes, brown atrophy of the heart, and hematoma of the liver.

Besides the frequent complaint of severe pruritus, there is associated in the majority of eruptions, preceding or accompanying them, elevation of temperature, which may rise to as high as 106 F. Like the eruption, this so-called drug fever usually appears after the seventh day of sulfonamide therapy. Drug fever, being in most cases a sensitization phenomenon, develops rapidly after readministration of the drug.

Incidence of Skin Eruptions

Although there is agreement among investigators about the fact that cutaneous reactions are produced most frequently by sulfathiazole and least frequently by sulfadiazine, all the sulfonamide compounds have been observed to cause serious reactions and even death. Among 500 patients treated with sulfa drugs, Dowling and Lepper[24] have noted the following incidence of dermatitis, fever, and/or conjunctivitis: from sulfathiazole, 6.2 per cent; from sulfapyridine, 2.4 per cent; from sulfadiazine, 2 per cent. Long[1] has observed in a large series of patients the following incidence of eruptions: following sulfathiazole therapy, 5.2 per cent; sulfanilamide, 2.2 per cent; sulfapyridine, 2 per cent; and sulfadiazine, 1.3 per cent. In

the course of sulfathiazole therapy, Volini and associates[23] found cutaneous reactions in 3.8 per cent, and Weinstein and Domm[2] in 3.7 per cent of the patients. Park and Platts[25] have found the incidence of eruptions following sulfanilamide therapy to be 4.3 per cent, that following sulfapyridine, 1.9 per cent. Costello[18] observed skin eruptions in 10 per cent of the cases in his series which were treated with sulfathiazole.

These figures, however, refer mostly to series of individuals receiving their first course of sulfonamide therapy. Analyses of large groups of patients who are following a second or third course of treatment with the drugs would reveal a very much higher incidence of cutaneous reactions, for the sulfonamides sensitize a high percentage of persons. Drug fever, because it is a sensitization phenomenon, may serve as an indication for the approximate incidence of cutaneous sensitization. Thus Lyons and Balberor[26] have found among 53 patients who had tolerated the first course of sulfathiazole, consisting of an initial dose of 4 Gm. followed by 1 Gm. every four hours during a period on an average of 5⅘ days, 19 patients—i.e., 36 per cent—who developed severe fever reaction during the second course of the drug therapy.

While the eruption and the drug fever, which appear for the first time early in the course of sulfonamide therapy, are usually mild and disappear rapidly if the drug administration is discontinued, it should be noted that the sensitization reaction, which takes place when the drug is continued or is readministered after a certain interval, is fraught with danger. The eruption which reappears at this period may be much more severe in character and may be associated with other serious by-effects like acute hemolytic anemia or agranulocytosis. Thus in the case reported by Weinstein and Domm[2] the patient, who in the presence of a macular rash had received by an oversight an additional 4 Gm. of sulfathiazole, developed within twenty-four hours a vesicular, bullous, and exfoliative dermatitis which led to death within a few days.

It should be known that sensitization of the skin and other organs takes place not only by oral administration of the sulfa drugs but also by local external application in the form of ointments. Cohen, Thomas, and Kalisch,[27] Miller,[12] and Livingood and Pillsbury[28] have reported cutaneous sensitization following application of sulfathiazole ointment to the skin. They all warn against the use of these drugs in minor conditions. For should the patient become sensitized it will be impossible for him to benefit from the sulfa drugs at some future time when he may be afflicted with serious illness.

Thus drug fever and eruption have to be considered as danger signals. They may indicate sensitivity of the skin to the sulfonamides or they may be forerunners of other serious toxic reactions like agranulocytosis. Irving,[29] pointing out this fact, demands from medical insurance companies great interest in this question of sulfa-drug sensitization.

It is of important interest whether ingestion of one sulfa drug sensitizes the patient to the other sulfonamide compounds also. This is impossible to predict as it varies in different individuals. The 2 cases of Haviland and Long,[22] in whom sulfathiazole therapy had to be interrupted because of a maculopapular eruption in one and urticaria in the other, showed exacerbation of these eruptions when sulfapyridine was given. Among the series of cases investigated by Costello[18] one patient who reacted with a diffuse erythematous eruption following sulfathiazole therapy developed erythema nodosum when sulfadiazine was substituted. In the report of Lyons and Balberor,[26] 5 patients who developed drug fever following sulfathiazole tolerated sulfapyridine and sulfanilamide without any reaction.

Case Reports

Case 1.—W. M., a colored boy aged 14, was admitted to Sydenham Hospital on February 3, 1942, with a generalized pruritic eruption of three days' duration. Past and family history were negative, particularly in regard to hay fever, asthma, or any allergic cutaneous manifestations.

Present history: One month previously the patient had contracted gonorrheal urethritis for which he had received since January 8, 1942, sulfanilamide by mouth. During the first two weeks 0.5 Gm. of the drug was administered four times daily and during the next eleven days three times daily. Thus he received a total of 45 Gm. of sulfanilamide within twenty-five days.

On February 1, two days before admission to the hospital and twenty-three days after the commencement of sulfanilamide therapy, the patient noticed swelling of the upper lip and some pruritic lesions on the left wrist which were soon followed by a generalized pruritic eruption. After the appearance of the eruption, the boy still continued to take sulfanilamide for two more days.

Examination: On admission to the hospital the patient appeared desperately ill. His temperature was 104 F., pulse 90, respiration 40, and the blood pressure 116 systolic by 70 diastolic. The heart and lungs were normal. There was no enlargement of the liver and spleen and no other abdominal abnormality. Except for submaxillary adenitis, no other lymph glands were palpable.

The skin presented a universal eruption of lentil- to pea-sized flat papules and occasional vesicles,

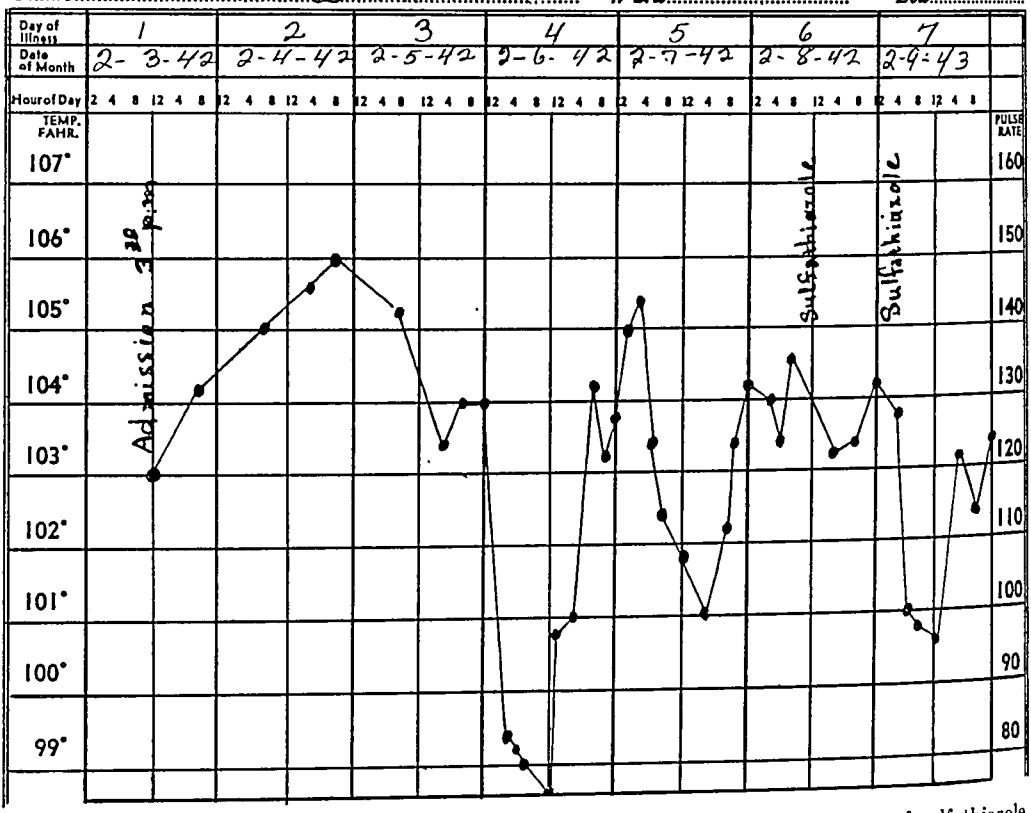

CHART I. Case 1. Drug fever from sulfanilamide. Not aggravated by administration of sulfathiazole.

which involved most profusely the face and extensor surface of the upper extremities, particularly of the hands. The mucous membranes of the mouth showed a profuse eruption of vesicles and were covered with exudate. The conjunctivae were chemotic, and the corneae appeared hazy. There was considerable discharge from the eyes. A diagnosis of dermatitis medicamentosa due to sulfanilamide was made.

Laboratory examination showed a normal urine. The blood count was 4,000,000 erythrocytes and 11,000 leukocytes; the hemoglobin content was 78 per cent (13.3 Gm.). The differential count showed 25 per cent neutrophil bands, 61 segmented neutrophils, 5 lymphocytes, and 7 per cent monocytes. The blood level of sulfanilamide was 0.8 mg. per cent. The blood chemistry showed 15.8 mg. per cent urea nitrogen, 503 chlorides, 153 cholesterol, and 56 mg. per cent cholesterol esters. The icteric index was 6; carbon dioxide (volume, per cent) was 43. The blood culture was sterile. The flocculation tests for syphilis were normal.

Course of illness: During the next few days the condition of the patient became steadily worse. The temperature rose on February 4 to 106 F. and dropped slightly on February 5 (Chart 1). On this day the pulse became weak and irregular and the respiration rapid, but the blood pressure was maintained. The patient first appeared stuporous, then became delirious. The skin lesions changed to vesicles and bullae, which became confluent. The eyes, nose, mouth, and lips produced bloody discharge and were covered with bloody crusts (Fig. 1). The nostrils were clogged. The breathing was rattling. Ophthalmologic examination by Dr. Kronenberg revealed denudation of the epithelium of the conjunctivae in many areas, cloudiness of the corneae, and loss of some of the corneal epithelium.

Following intravenous infusion of a saline solution of glucose, administration of oxygen, and other treatment, the condition of the patient improved slightly. On the next day, February 6, the temperature fell to normal, and the general condition

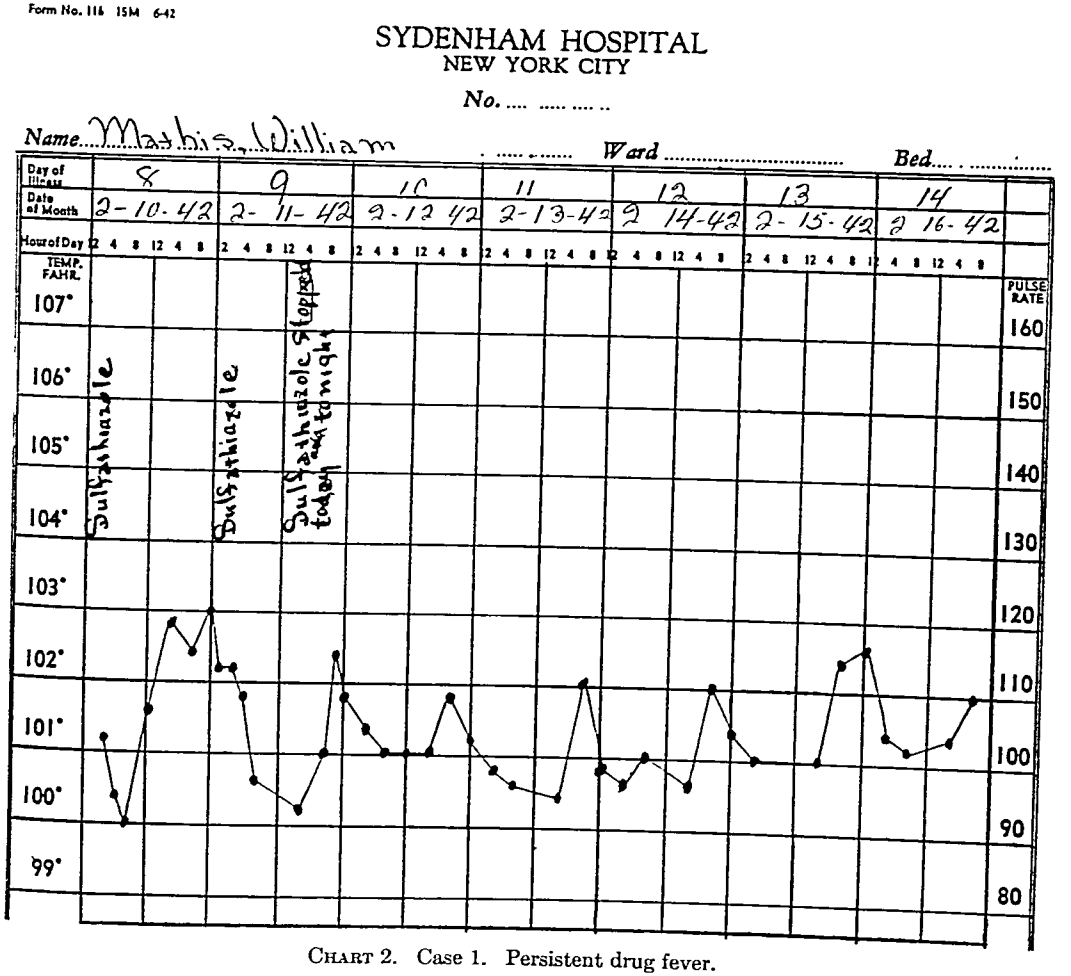

CHART 2. Case 1. Persistent drug fever.

improved rapidly. The skin lesions assumed more and more a vesicular and bullous type. Examination of serum from a bulla showed a trace of sulfanilamide.

On February 7, however, the temperature rose again to 105.4 F., and the patient became irrational and could not be controlled by hypnotics or sedatives. The throat became clogged with mucus. At times Cheyne-Stokes breathing was present. The bullous lesions of the skin became confluent, broke, and exposed large areas of raw skin. On the following day the temperature dropped somewhat but continued to be spiking during the next few days, reaching a maximum of 103 to 104 F. Because of the continuous septic type of temperature, the internist considered the possibility of some superimposed bacterial infection, in spite of the negative blood cultures and the normal roentgenograms of the chest. He advised, therefore, the administration of sulfathiazole orally with an initial dose of 2 Gm., followed by 1 Gm. every four hours. The temperature, however, continued to be of septic type, varying between 100.6 F. in the morning and 103.4 F. in the evening on February 9, and between 100 and 103 F. on February 10 (Chart 2). On the third day of sulfathiazole therapy the blood level of the drug was 2.5 mg. per cent. After the administration of a total of 23 Gm. of sulfathiazole, the drug was discontinued on the fourth day. The temperature continued to vary between 100, 101, and 102 F. The patient's general condition, however, as well as that of his skin, gradually improved. On February 15, the skin started to exfoliate, like that of dermatitis exfoliativa. On February 20, the morning temperature became normal, but the evening temperature continued to be above normal until March 8, 1942.

Among the different laboratory examinations carried out during the illness of the patient the following abnormal data were noted: On February 9 the urine showed marked albuminuria and a small amount of urobilinogen. On the same day the blood examination revealed a hemoglobin content of 66 per cent (11.3 Gm.) and 3,440,000 erythrocytes, and on March 9 similar figures were obtained. On one occasion there were 3 per cent neutrophil

FIG. 1. Case 1. Vesiculobullous eruption involving the mouth, nose, and eyes.

myelocytes and 3 per cent metamyelocytes. On another occasion 6 per cent eosinophils were noted. Dr. Jacob Heiman called attention to the variation in the figures for cholesterol and esters of the blood, which on February 5 were 153 and 43 mg. per cent, respectively, and on February 10, 122 and 38, while on March 9, the figure for cholesterol rose to 199 and that for cholesterol esters to 83 mg. per cent.

On March 16, after an illness of more than six weeks, the patient was discharged from the hospital in a fairly good general condition. The skin presented a generalized eruption of hyperpigmented macules which persisted when he was seen many months later, and a large plaque of depigmentation with some keloidal formation on the dorsum of his left hand.*

SUMMARY AND COMMENT ON CASE 1

The essential facts in the history of this case may be summarized as follows: A boy, aged 14, developed a pruritic eruption following ingestion of more than 40 Gm. of sulfanilamide which he had received during a period of three and a half weeks for the treatment of gonorrheal urethritis. He continued to take the drug for two more days after the appearance of the eruption. The eruption, which was first papular, became universal, changed to a vesicular and bullous form, and involved the mucous membranes of the mouth and nose, and also the conjunctivae, sclerae, and corneae. It was associated with high fever of septic type which persisted for about thirty-five days. The patient was gravely ill during the first nine days of his stay in the hospital, was delirious, and showed signs of severe intoxication. On thorough investigation no other objective changes could be found which might have been responsible for the severe illness except the cutaneous involvement, associated possibly with the effect of the drug on the central nervous system. However, in the belief that there might nevertheless be a superimposed bacterial infection, sulfathiazole was administered, during a period of several days, in the total amount of 23 Gm., but the septic type of fever continued for more than a month.

It is evident that the gradual improvement in the condition of the patient was not due to the sulfathiazole therapy but rather came about in spite of the treatment. However, the fact that the patient did not become worse following the administration of sulfathiazole indicates that the previous ingestion of sulfanilamide had produced sensitization only to this compound and not to sulfathiazole.

The fact that soon after the development of the reaction the blood level of sulfanilamide was only 0.8 mg. per cent probably indicates that we are dealing here with an allergic phenomenon rather than with a purely toxic effect of the drug.

It is not improbable that the serious cutaneous eruption and the illness of the patient could have been prevented, or at least their severity reduced, if the patient had been observed more closely and the administration of the drug had been stopped immediately at the first appearance of the reaction. It has also to be seriously considered whether this prolonged period of treatment of gonorrheal urethritis is not unwise, instead of the shorter period of from five to ten days advised by the Department of Health of the City of New York.

Case 2.†—R. P., an American woman, aged 47, a nurse, developed on September 3, 1942, a generalized bullous eruption while recuperating at Sydenham Hospital from an operation for a hernia of the abdominal wall.

Past history: There was a past history of numerous operations performed on the patient: at the age of 20, appendectomy; four years later, tonsillectomy; at the age of 27, myomectomy of the uterus; and seven years before, hysterectomy. Six years previously the patient had received a series of deep x-ray exposures to the ovaries because of a persistent mastitis of one year's duration. For the past six years she had been suffering on and off from furunculosis.

* The patient was presented by the author at the Bronx Dermatological Society on March 26, 1942. (Arch. Dermat. & Syph. 46: 161 (Sept.) 1942.)

† The patient was presented before the Manhattan Dermatological Society in February, 1943. (Presentation and discussion to be published in the *Archives of Dermatology and Syphilology.*)

Present history: On July 22, 1942, the patient applied a 10 per cent sulfathiazole ointment to one of the furuncles on her thigh. Several days later she noticed small bullae on the left eyelid, on and inside the nose, and in the mouth. On August 3, a carbuncle on the back of the neck was incised by the surgeon and some powder inserted into the wound. Several new bullae, which were flaccid or broken, appeared on the face. These lesions were diagnosed as bullous impetigo and cleared up under the use of ammoniated mercury ointment.

On August 17, 1942, the patient was operated on at Sydenham Hospital for an incisional hernia of the abdominal wall, at the end of which operation sulfanilamide powder was deposited into the wound before the skin was closed.

The patient was recuperating satisfactorily from the operation until August 29, when she applied a 10 per cent sulfathiazole ointment to a sore on the mucous membrane of the nose. On the following day a few bullae appeared on the back of her neck, and later the skin around the left eye became edematous and developed a few pea-sized bullae which soon broke and resembled pyodermic lesions. A 5 per cent sulfathiazole ointment was prescribed, but soon its use was discontinued, for the patient developed new bullae not only on the eyelids and the face but also on the mucous membrane of the mouth, in the perianal region, and on the abdomen, where the bullae were arranged in the form of a chain along the incisional scar. The eruption was associated with severe pruritus. A diagnosis of dermatitis medicamentosa due to sulfathiazole or and sulfanilamide was then made.

Course of illness: During her stay in the hospital, until December 12, 1942, the patient frequently developed new crops of bullae, which appeared on normal skin and involved the face, the trunk, the axillas, the groins, the anus and vulva, the palms and soles, the back of the hands and feet, the forearms and legs, the elbows, the scalp, and the mucous membranes of the mouth (Fig. 2). Most frequently the appearance of new lesions was preceded by severe pruritus. On several occasions numerous nonpruritic, slightly raised erythematous macules and plaques, of one inch in diameter, appeared on her trunk, which looked like lesions of erythema multiforme. Her temperature varied between normal, 100 F., and 101 F. This slight rise in temperature was associated with considerable weakness, which has gradually improved following blood transfusions, injections of liver extract, calcium gluconate, autohemotherapy, and sodium arsenate.

On December 12, the patient was discharged from the hospital as improved, but she has continued to be under my observation. During the five months after she left the hospital, the patient gained considerably in strength following numerous blood transfusions and administration of sodium arsenate, liver extract, and iron. However, the eruption of crops of bullae continued to appear frequently. Although in diminished number, the bullae caused great discomfort, for they were located particularly on her feet and soles, causing great difficulty in walking. Her feet and the mucous membranes of her mouth are hardly ever free of bullae. Some of the bullae contain clear fluid; others are hemorrhagic, and their size varies between $\frac{1}{2}$ inch and 3 inches in diameter (Figs. 3 and 4). The trunk shows only at rare occasions unbroken bullae, for the lesions consist mostly of crusts and areas denuded of skin. In place of previous lesions, there are erythematous macules which show atrophy and milia. The evening temperature of the patient has frequently been 100.5 F.

FIG. 2. Case 2. Showing broken bullae and erythematous atrophic spots left from previous lesions, three months after beginning of eruption.

Laboratory examination: The blood count revealed on numerous occasions a moderate diminution in the number of erythrocytes and in hemoglobin content, while the leukocytes showed a moderate increase in number, and the differential count was about normal. The urine examination gave normal findings except for an increased urobilinogen content on one occasion. The blood chemistry examination showed a normal content of cholesterol, cholesterol esters, sugar, nonprotein nitrogen, and sodium chloride. The icterus index was 6.1.

A few days after the appearance of the generalized eruption, the blood serum showed a trace of sulfanilamide, but none was found in the serum from the bullae. The phytopharmacologic test of the serum was reported by Dr. David I. Macht as nontoxic—i.e., acting as normal blood serum. The phytotoxic index was 71 per cent.

Recently a patch test was made on the skin of the back with a saturated solution of sulfanilamide, and

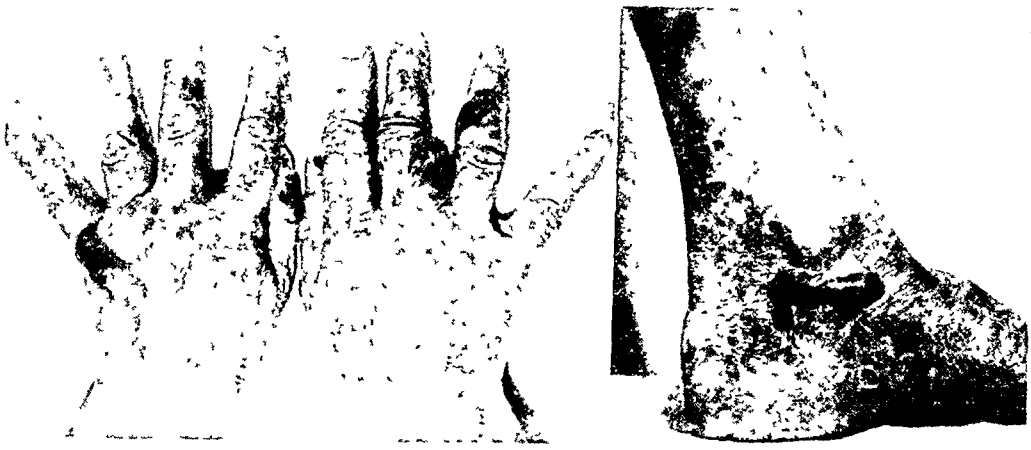

FIG. 3 Case 2. Showing large bullae and healed lesions, seven months after beginning of eruption
FIG. 4. Case 2. Showing large hemorrhagic bulla and numerous small bullae, seven months after beginning of illness.

twenty-four hours later a similar test was made with a saturated solution of sulfathiazole and a 5 per cent sulfathiazole ointment. There was no local reaction to these solutions or to the ointment. But about twelve hours after the application of sulfathiazole, a generalized pruritus developed, followed several hours later by an eruption of many bullae, particularly on the legs. A patch test with a 30 per cent potassium iodide ointment gave a negative result.

The easy separation of the epidermis following removal of adhesive from the patient's back as well as the fact that her feet when exposed to mechanical injury are particularly vulnerable indicate the presence of a modified Nikolsky sign.

COMMENT ON CASE 2

It is not certain whether the generalized bullous eruption which has persisted for eight months is due to cutaneous sensitization to sulfathiazole or sulfanilamide alone or to both. The assumption of a causative relation between the deposition of sulfanilamide powder into the operative wound and the development of the eruption two weeks later is disturbed by the fact that the patient gives a history of development of bullae following application of sulfathiazole ointment to the skin or to the mucous membrane of the nose. Another disturbing fact is that the generalized eruption was also preceded by application of sulfathiazole ointment to the mucous membrane of the nose and the skin. The presence of cutaneous sensitization to sulfathiazole is unquestionable, as in addition to the history given by the patient the author has observed personally the development of bullae following the use of the sulfathiazole ointment There are three explanations possible for the generalized bullous eruption in this patient:

1. The eruption may be due solely to sulfathiazole sensitization which has been produced by several applications of sulfathiazole ointment to the skin or mucous membranes. The deposition of sulfanilamide powder into the operative wound is coincidental and not causative.

2. The eruption may be due to sulfanilamide toxicity or sensitization which has developed gradually because of absorption of the drug from the incisional area over a period of many days

3. The third explanation may be that the sulfathiazole sensitization has changed the skin and prepared the way for a reaction to sulfanilamide powder.

Of the three explanations of the eruption, I am inclined to favor the third one, for I believe that the sensitization to sulfathiazole, produced by repeated applications of ointments to lesions on the skin and on mucous membranes, has contributed to the generalized eruption by making sensitization to sulfanilamide possible. The chain of bullae appearing along the incisional scar at the beginning of the illness may possibly be an indication of the causative relation between the sulfanilamide powder deposited in the wound and the bullous eruption.

The persistence of the eruption as long as eight months after the use of the drug does not speak against the diagnosis of dermatitis medicamentosa. Persistence and even progression of drug eruptions are a known fact and have been observed in reactions produced by other drugs, like iodides, bromides, and arsenic. This has been brought out by Sulzberger[4] and others In the fatal case of pemphigus foliaceus reported

by Wien and Lieberthal[17] the eruption persisted for six months, resulting in death.

On clinical observation alone one would not hesitate to consider seriously the diagnosis of pemphigus vulgaris. But the history and the facts already discussed speak against this diagnosis. The normal phytotoxic test of the blood in this patient would be, according to Macht,[30] also a point in favor of the diagnosis of sulfonamide eruption rather than that of pemphigus vulgaris.

Conclusions

When one considers that in 1941, according to Long,[1] more than 1,000,000 pounds of sulfanilamide and sulfathiazole were sold in this country, in addition to considerable amounts of sulfapyridine and sulfadiazine, and when one reflects that many thousands of lives are being saved by these drugs, the incidence of serious toxic reactions and even the several thousand fatalities known to have been produced by the drugs may seem negligible. But looking at absolute figures and considering the enormous number of individuals who have been and are unknowingly sensitized to these drugs and are potential victims of illness and death when at some future time the drug is given to them, one sees the necessity of preventing or reducing to a minimum the toxic and fatal reactions of the sulfonamides.

From the above review of the cases in the literature and from the observation of the two cases reported in this paper, one may conclude that the following rules should be observed in regard to administration of sulfonamides:

1. No trivial illness should be treated with these drugs. Spraying and application of sulfonamide drugs in minor nose and throat conditions and the common use of sulfonamide ointments in all kinds of minor skin wounds and infections should be condemned. To cause sensitization from these sprays and ointments is particularly unforgivable when one considers the fact that most of these conditions respond as well or better to other harmless medication. It is shocking to know of the case of a young girl who died of sulfathiazole intoxication when this drug was used for the treatment of her acne vulgaris (Lederer and Rosenblatt[31]).

2. There is no justification for using these drugs prophylactically, in conditions like the venereal diseases, as recommended recently for the Army by Loveless and Denton,[32] for this prophylactic administration of the drugs will, of course, have to be repeated many times, thus exposing the soldier or sailor to the dangers of sensitization. Taylor[33] has the merit to have called attention to another unjustified prophylactic use of these drugs—namely, the routine deposition of sulfonamide powder in clean operative wounds or in appendectomy.

3. The dosage of the drug and the period of administration should not exceed that necessary to cope with the infection. The smaller the total amount which is administered and the shorter the period of administration, the less are the chances for toxic and sensitization reactions to develop. That larger doses do not always yield more beneficial results in infection than smaller doses has been shown by Dowling and Lepper.[24] These authors found that sulfadiazine in the dosage of 3 Gm. daily is as effective in the treatment of pneumococcic pneumonia as when 6 Gm. are given daily. I believe that if a series of conditions other than pneumococcic pneumonia were analyzed, one might find that the optimal dosage of the sulfa drugs in many diseases is lower than is usually thought necessary for successful therapy.

4 The use of the drugs should be avoided as much as possible by elderly patients, by those whose kidneys or liver are damaged, and by those who are known to be allergic to other drugs.

5. The blood and the urine of the patient to whom a sulfa drug is administered should be frequently examined in order to detect, as early as possible, pathologic changes in the blood and the renal system. At the first observation of an eruption or drug fever, in the course of the sulfonamide therapy for a serious illness which requires urgently the use of the drug, the patient should be closely watched. In less serious diseases sulfonamide therapy should be immediately discontinued. The patient may then quickly recover from the drug reaction. For one should keep in mind that continuation of treatment in the presence of even a mild reaction may exacerbate this reaction into a more severe and serious one and may even prove fatal.

Summary

1. Two cases of bullous eruption following sulfonamide therapy are reported, one of which resembled pemphigus vulgaris.

2. The literature on cutaneous reactions produced by the sulfonamides is reviewed, and the mechanism of these reactions is discussed.

3. Conclusions are drawn in regard to rules to be observed at the administration of sulfa drugs, in order to prevent serious reactions and possible death.

NERVOUS AND MENTAL SEQUELAE OF TROPICAL DISEASES

By insisting on certain precautions in personal hygiene and by preparing soldiers and sailors for meeting the moral hazards common in the tropics, many of the nervous and mental aftereffects from tropical diseases that are menacing members of the armed forces in various parts of the world can be prevented, Lieutenant Commander James L. McCartney (M.C.), USNR, says in *War Medicine*.

"American physicians, both in and out of the armed forces," Dr. McCartney says, "should familiarize themselves with tropical diseases, and especially the neuropsychiatric sequelae, for many men will return to America from the tropics with permanent neuropsychiatric disabilities. . . .

"Tropical diseases are so named because of their almost exclusive preponderance in that geographic belt lying between 23° 27′ north and south of the equator, known as the tropical zone, and in the bordering zones, known as the subtropical regions. On the other hand, with speeding up of transportation and the inevitable return of the majority of the American armed forces to their homeland, these diseases may find a foothold in less tropical climes. Fortunately for the American people, nearly 50 per cent of the tropical diseases are parasitic in origin, and 25 per cent of these disorders are arthropod (insects, spiders, crustaceans, etc.) borne. But there are yet 50 per cent of the diseases that may be brought back by the American forces, and most certainly many men will bear the sequelae of permanent disability. One has but to review history to be impressed by the fact that these diseases have repeatedly migrated into temperate zones and in their outrageous wanderings have played havoc among the peoples of the earth and accursed civilization and progress.

"That these diseases many times show neurologic sequelae is a well-known fact, although these degenerative changes have not always been recorded by authors on tropical diseases."

Among the tropical health hazards mentioned by Dr. McCartney is the fact that residence in the tropics sooner or later causes a reduction in the blood pressure and the basal metabolic rate of an appreciable number of persons. Then there is heat fever, resulting from the powerful heating effect of the tropical sun on the body, wherein the heat-regulating mechanism becomes overtaxed and so fails to keep the body below the temperature at which damage is done to body cells, especially to nerve cells. The mental changes from this condition are like those occurring in senility, and severe headaches and epileptic-like convulsions may persist for months or years. Another hazard of the tropical sun is the temporary or permanent blindness of parts of the eye that may result from light-stroke. Overstimulation by bright light over any length of time may cause night blindness. The latter is a neuropsychiatric problem in the tropics of military import, because persons suffering from this condition may have perfectly normal vision during the day and be useless as observers after the sun has gone down. Night flying, night watch, and night sentry duty for such victims are out of the question.

"Young Americans arriving in tropical countries," Dr. McCartney says, "find a milieu totally different from their home environment. Moral standards are lowered; human values are hardly worth mentioning, and intemperances of every kind are the order of the day. . . . . The amoral environment is too much for the white man, for he finds it constantly about him. Sexual promiscuity is everywhere to be found, and as a result psychic conflicts and guilt feelings are set up in the white man's conscience. . . ."

Alcoholism has its relationship to sexual problems and its bearing on vitamin deficiencies in the tropics. There also are the hazards of food intoxication, or [illegible] may lead to neuropsychiatric sequelae, as may also infections of the blood stream. Malaria has numerous neurologic sequelae.—*A.M.A. News*

TROPICAL DISEASES—A POSTWAR HEALTH PROBLEM

THOMAS T. MACKIE, LIEUTENANT COLONEL, MC, USA

IT IS becoming increasingly evident that the war will exert a profound influence upon many aspects of medical service in the United States. The immediate effect, the dilution of physicians remaining in civil life incidental to the needs of the armed forces, is probably the least important. A second early effect is more significant, though perhaps less obvious The inescapable curtailment of postgraduate medical education entails interference with advanced training, and at least an interruption of the supply of replacements for the field of public health practice. By far the most important effect, however, and one, the full impact of which will not be felt until after the cessation of hostilities and demobilization, is the possible shift of disease endemicity and consequent changes in the responsibilities of individual practitioners and of public health agencies.

The implication inherent in the term "tropical medicine"—that it comprises a group of diseases restricted to the hot countries—is incorrect. Although in some instances climate acts as a limiting factor by virtue of its controlling effect upon the availability of suitable intermediate hosts and insect vectors, in many of the more important conditions the limiting factors are merely those of the level of sanitation and hygiene prevalent in the area Many important so-called tropical diseases are capable of establishing themselves in the temperate zone and flourishing There are numerous illustrations of this in the past. Yellow fever has occurred in epidemic form on the Atlantic seaboard as far north as Boston. Asiatic cholera has been epidemic throughout the area of the eastern and central states. Periodic epidemics of dengue fever are familiar about the Gulf of Mexico Outbreaks of bubonic plague have occurred in various of our seaports and this disease, in its sylvatic form, is widespread in the wild rodent population in the West, and has extended eastward across the Continental Divide. Until comparatively recent times, malaria was a familiar disease even in the northern states. Amebic and bacillary dysentery, long considered strictly tropical, are now recognized to have a world-wide distribution and to be prevalent wherever conditions permit fecal contamination of food and water. An endemic focus of filariasis, which produces tropical elephantiasis, has long existed in the vicinity of Charleston, South Carolina These illustrations demonstrate the fallacy of an assumption that so-called tropical diseases cannot extend widely beyond their present areas of recognized endemicity. These potentialities for widened endemicity, together with the extent of present military and naval operations in the tropics and subtropics, have created an increasing fear that our men returning from these areas after the war will be responsible for the introduction and wide extension of tropical diseases in the United States. Although certain of these conditions will be imported, there is an unfortunate tendency to overemphasize the hazard.

The first World War demonstrated that military operations cannot be undertaken in the tropics and subtropics without a high disease rate unless special precautions are taken. Thus, in Macedonia, malaria was in large part responsible for the military stalemate between the Allied armies and the German armies. Similarly, bacillary dysentery played an important part in failure of the Gallipoli campaign. Amebiasis proved to be of less importance The infection rate among troops returning from the Near East is reported to have been approximately 10 per cent [1] The marked difference in morbidity is attributable to the fact that amebic infection, except under highly specialized and unusual conditions, does not become epidemic.

The present war involves the mobilization of large numbers of men in many regions where tropical diseases are endemic The provision of complete protection against infection would constitute an enormous problem in preventive medicine under peacetime conditions. In wartime, and in the face of combat conditions, especially those of jungle warfare, and those attendant upon the rapid movement of mechanized operations, the problem is infinitely more difficult Although great advances have been made in the field of immunology which permit protection against a number of important diseases, we have as yet no means of effective immunization against the protozoan infections, the parasitic helminths, and certain diseases caused by bacteria and other agents endemic in the tropical theaters of operations. The risk of these conditions, however, has been greatly minimized by marked improvements in field sanitation, notably in connection with the provision of safe water and protection against insect vectors of disease. The equipment of troops with bed nets, head nets, gloves, insect repellents, and insecticides, and the application of suppressive treat-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 3, 1943

ment, should do much to control morbidity to malaria and prevent a repetition of the experience of the armies in Macedonia in the last war.

Exposure and infection, however, cannot be completely eliminated. Furthermore, in the case of certain tropical diseases the most efficient therapeutic procedures do not invariably, or in some instances even usually, eradicate the infecting organism. Malaria, due to Plasmodium vivax, may exhibit a late recurrence rate of over 50 per cent.[2] Although infections by P. falciparum, the causative agent of the dangerous tropical malaria, are more amenable to immediate therapy, chronic infections persisting for many months are not uncommon. In all of these chronic infections, gametocytes, the sexual form of the plasmodium which is infective to the anopheline mosquito, are commonly found in the peripheral blood.

Bacillary dysentery is widespread throughout the tropics and, undoubtedly, significant numbers of men will be infected. Fortunately the great therapeutic efficiency of the sulfonamide drugs has relegated this disease to a position of importance far inferior to that which it attained in the first World War. Extensive clinical trials, however, have demonstrated that they will not completely eliminate the carrier.

Amebiasis, likewise, is widely prevalent wherever bad conditions of sanitation exist. Complete eradication of the Endamoeba histolytica is frequently difficult in the absence of intensive therapy. Furthermore, a high proportion of individuals do not present the clinical picture of dysentery, and in fact may exhibit little evidence of the infection. Such infections may persist for many years and constitute a hazard to the carrier and a potential focus for dissemination.

It appears possible that typhoid fever may again assume some importance. It is highly endemic in many tropical regions. Past experience indicates that prophylactic vaccination will greatly reduce, although it will not completely climinate, morbidity to this disease. Furthermore, the resulting partial immunity considerably alters the clinical picture and complicates diagnosis, and it may augment the relative number of undiagnosed mild ambulatory cases. Although no figures are available concerning the incidence of the carrier state among vaccinated individuals, there is little reason to suppose that chronic infections will be eliminated. The observation that a larger proportion of immunized mice become temporary carriers than do nonimmunized mice[3] suggests that vaccination may even augment the relative numbers of healthy carriers.

Filariasis, due to infection by the Wuchereria bancrofti, is another widespread tropical disease to which numbers of our men will be exposed. Since we have as yet no effective therapeutic agent, chronicity is the rule and the microfilariae infective to the mosquito persist in the peripheral blood for considerable periods of time.

It is evident, therefore, that instances of these infections and possibly others may be anticipated among personnel returning from the various tropical theaters of war. It is obviously impossible to estimate the numbers which will be affected. The potential importance of this problem, however, is well recognized by the Army and Navy, and in cooperation with the United States Public Health Service detailed plans are in preparation to prevent seeding of the civilian population with infective returned individuals. No method of screening, however, will identify all cases. There is, therefore, a very real responsibility devolving upon the individual practitioner who must familiarize himself with the diagnosis and treatment of tropical diseases, and upon public health agencies which must exercise effective control of the epidemiologic factors concerned in the spread of these conditions. Such cooperative action on the part of the services, the medical practitioner, and local public health agencies should afford more than adequate protection.

It is necessary, however, that individual physicians have some familiarity with the epidemiology of the more important tropical diseases. Many of them are transmitted by insects. For some, an arthropod is a required intermediate or definitive host in which the causative agent carries out a part of its life cycle. In other instances, insect transmission is purely mechanical. Certain of these conditions are spread by contaminated water and food and others through soil pollution.

It follows, therefore, that any impact which tropical medicine may exert upon the United States will be felt predominantly in rural areas where the general level of sanitation is inferior to that of large urban centers. It is here that optimal conditions exist for insect propagation. The housefly and the anopheline and culicine mosquitoes are the most important disease vectors pertinent to this discussion.

The widespread use of unscreened privies and the usual methods for storage of manure are conducive to extensive fly breeding. The ordinary housefly is an important vector of the intestinal bacterial and protozoal infections, and of certain helminthic infestations. Its habits of feeding upon human excreta and regurgitating in the course of the subsequent feed, together with its flight range, permit it to carry these agents considerable distances from the original source. A further factor of importance in the potential spread of certain of these conditions is the almost

universal practice, especially in small communities, of discharging crude sewage into streams and rivers. This entails extensive water pollution and considerably augments the hazard of spread of the enteric diseases.

Malaria in the United States is transmitted predominantly by the Anopheles quadrimaculatus which is a satisfactory host both for P. falciparum and P. vivax. Its range extends as far north as New Hampshire, southern Ontario, and Minnesota. It accepts a variety of breeding places including fresh-water pools, ponds, lakes, swamps, and even brackish marshes.[4] It hibernates through the winter in barns, cellars, and other protected spots. Furthermore, the resistance of the plasmodia in the oocyst stage under conditions of not too extreme cold permits them to overwinter in the hibernating insect and to mature in the following spring. Both of these factors, therefore, combine to carry infection over the winter and to provide for transmission in the subsequent spring and summer.

Filariasis is transmitted by a variety of different mosquitoes, three of which, Aedes aegypti, Culex quinquefasciatus, and C. pipiens, are common domestic pest mosquitoes in the United States. C. quinquefasciatus is the most abundant night-biting house mosquito in the southern states, extending north into Tennessee and Virginia, where its range overlaps that of its near relative C. pipiens, the common house mosquito of the north.[5] These two culicines are particularly common vectors of filariasis in many parts of the world.[1]

From this superficial scrutiny of some of the medical problems associated with the war, certain probabilities and possibilities appear. It is evident that numbers of individuals returning from the tropics will carry infections which may be transmissible in this country providing necessary epidemiologic conditions are fulfilled. Although the numbers of such individuals cannot be foretold at present, the mechanism set up by the Army, the Navy, and the United States Public Health Service should amply protect against extensive exposure of civilian population groups. This barrier, however, must be supplemented by local public health agencies and by the individual practitioner.

Implicit in such protection of the community, and of the infected individual himself, is the need for a much wider teaching of tropical medicine, and for instruction in the epidemiology of tropical diseases. The inclusion of these subjects in the undergraduate medical curriculum does not meet the needs since it does not reach the practicing physician. Since the problem affects so intimately both the individual practitioner and the public health agency, a simple solution should be available. A cooperative arrangement between county medical societies, state departments of health, and medical schools should permit the preparation of a series of symposiums covering the more important tropical diseases. Presentation of such a series of programs at regular meetings of county medical societies would do much to inform practicing physicians concerning these unfamiliar conditions, and greatly facilitate the handling of problems in this field of medicine which may arise in the future.

Discussion

Dr. James E. Perkins, *Director, Division of Communicable Diseases, New York State Department of Health*—Lt. Col. Mackie has presented an excellent summary of the tropical disease problem which medical practitioners and public health administrators in New York State may face as the result of the return of many New York State residents who are in the armed forces in tropical areas. In presenting this problem, Lt. Col. Mackie is in a difficult position since he wants to warn of a genuine hazard and still he does not wish to alarm physicians and the public unnecessarily. Those of us who have to handle publicity with regard to the relatively uncommon but nevertheless existent diseases of trichinosis, tularemia, and botulism can symphathize with him in this position.

This problem of the increase in tropical diseases divides itself roughly into two parts, it seems to me: (1) those diseases which are of public-health importance—that is, those which are likely to spread to others from the foci represented by men returning from the tropical areas; and (2) those which are not of public-health importance, since they will not be communicated to others. These latter diseases, nevertheless, will present difficult diagnostic and treatment problems to the medical practitioner.

I shall consider only those of public-health importance since this is my immediate concern. I might state, first, that we are well aware of this problem as evidenced by the fact that a year ago, after the Annual Meeting of the State Medical Society in New York City, a refresher course in tropical medicine was given to the district state health officers, arranged for us at the Cornell Medical College by Dr. Wilson G. Smillie, and with Dr. Mackie, incidentally, as one of the speakers. We also have purchased and installed in each district

ment, should do much to control morbidity to malaria and prevent a repetition of the experience of the armies in Macedonia in the last war.

Exposure and infection, however, cannot be completely eliminated. Furthermore, in the case of certain tropical diseases the most efficient therapeutic procedures do not invariably, or in some instances even usually, eradicate the infecting organism. Malaria, due to Plasmodium vivax, may exhibit a late recurrence rate of over 50 per cent.[2] Although infections by P. falciparum, the causative agent of the dangerous tropical malaria, are more amenable to immediate therapy, chronic infections persisting for many months are not uncommon. In all of these chronic infections, gametocytes, the sexual form of the plasmodium which is infective to the anopheline mosquito, are commonly found in the peripheral blood.

Bacillary dysentery is widespread throughout the tropics and, undoubtedly, significant numbers of men will be infected. Fortunately the great therapeutic efficiency of the sulfonamide drugs has relegated this disease to a position of importance far inferior to that which it attained in the first World War. Extensive clinical trials, however, have demonstrated that they will not completely eliminate the carrier.

Amebiasis, likewise, is widely prevalent wherever bad conditions of sanitation exist. Complete eradication of the Endamoeba histolytica is frequently difficult in the absence of intensive therapy. Furthermore, a high proportion of individuals do not present the clinical picture of dysentery, and in fact may exhibit little evidence of the infection. Such infections may persist for many years and constitute a hazard to the carrier and a potential focus for dissemination.

It appears possible that typhoid fever may again assume some importance. It is highly endemic in many tropical regions. Past experience indicates that prophylactic vaccination will greatly reduce, although it will not completely eliminate, morbidity to this disease. Furthermore, the resulting partial immunity considerably alters the clinical picture and complicates diagnosis, and it may augment the relative number of undiagnosed mild ambulatory cases. Although no figures are available concerning the incidence of the carrier state among vaccinated individuals, there is little reason to suppose that chronic infections will be eliminated. The observation that a larger proportion of immunized mice become temporary carriers than do nonimmunized mice[3] suggests that vaccination may even augment the relative numbers of healthy carriers.

Filariasis, due to infection by the Wuchereria bancrofti, is another widespread tropical disease to which numbers of our men will be exposed. Since we have as yet no effective therapeutic agent, chronicity is the rule and the microfilariae infective to the mosquito persist in the peripheral blood for considerable periods of time.

It is evident, therefore, that instances of these infections and possibly others may be anticipated among personnel returning from the various tropical theaters of war. It is obviously impossible to estimate the numbers which will be affected. The potential importance of this problem, however, is well recognized by the Army and Navy, and in cooperation with the United States Public Health Service detailed plans are in preparation to prevent seeding of the civilian population with infective returned individuals. No method of screening, however, will identify all cases. There is, therefore, a very real responsibility devolving upon the individual practitioner who must familiarize himself with the diagnosis and treatment of tropical diseases, and upon public health agencies which must exercise effective control of the epidemiologic factors concerned in the spread of these conditions. Such cooperative action on the part of the services, the medical practitioner, and local public health agencies should afford more than adequate protection.

It is necessary, however, that individual physicians have some familiarity with the epidemiology of the more important tropical diseases. Many of them are transmitted by insects. For some, an arthropod is a required intermediate or definitive host in which the causative agent carries out a part of its life cycle. In other instances, insect transmission is purely mechanical. Certain of these conditions are spread by contaminated water and food and others through soil pollution.

It follows, therefore, that any impact which tropical medicine may exert upon the United States will be felt predominantly in rural areas where the general level of sanitation is inferior to that of large urban centers. It is here that optimal conditions exist for insect propagation. The housefly and the anopheline and culicine mosquitoes are the most important disease vectors pertinent to this discussion.

The widespread use of unscreened privies and the usual methods for storage of manure are conducive to extensive fly breeding. Discussion

Dr. James E. Perkins, *Director, Division of Communicable Diseases, New York State Department of Health*—Lt. Col. Mackie has presented an excellent summary of the tropical disease problem which medical practitioners and public health administrators in New York State may face as the result of the return of many New York State residents who are in the armed forces in tropical areas. In presenting this problem, Lt. Col. Mackie is in a difficult position since he wants to warn of a genuine hazard and still he does not wish to alarm physicians and the public unnecessarily. Those of us who have to handle publicity with regard to the relatively uncommon but nevertheless existent diseases of trichinosis, tularemia, and botulism can symphathize with him in this position.

This problem of the increase in tropical diseases divides itself roughly into two parts, it seems to me: (1) those diseases which are of public-health importance—that is, those which are likely to spread to others from the foci represented by men returning from the tropical areas; and (2) those which are not of public-health importance, since they will not be communicated to others. These latter diseases, nevertheless, will present difficult diagnostic and treatment problems to the medical practitioner.

I shall consider only those of public-health importance since this is my immediate concern. I might state, first, that we are well aware of this problem as evidenced by the fact that a year ago, after the Annual Meeting of the State Medical Society in New York City, a refresher course in tropical medicine was given to the district state health officers, arranged for us at the Cornell Medical College by Dr. Wilson G. Smillie, and with Dr. Mackie, incidentally, as one of the speakers. We also have purchased and installed in each district

office copies of the recently revised two-volume edition of *Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases* by Strong (The Blakiston Company, Sixth edition, 1942), which, incidentally, is an excellent, up-to-date, exhaustive text on tropical medicine.

Tropical diseases of public-health importance may be divided into those in which an intermediate host is necessary and those in which no such intermediate host is involved.

Among those in which there is no intermediate host, we may consider first the venereal diseases. Although we may have some bizarre venereal diseases brought back by members of the armed forces, at least there will be no explosive outbreak, due to the mode of spread compared with diseases transmissible through water and milk. As a matter of fact, many venereal diseases, formerly thought to be rare in New York State, have been found to be quite prevalent; lymphogranuloma venereum, for example, has been found to be very prevalent in New York City, particularly among certain groups.

As to the enteric tropical diseases, I have difficulty in believing that they will be any great menace to the civilian population, unless environmental sanitation barriers which we have so effectively built up in the past few decades are destined to be destroyed or otherwise made ineffective. I refer to our water filtration plants, sewage disposal systems, milk pasteurization plants, etc. In view of the present trend of events in the war, such destruction of our environmental sanitation devices seems to me to be very unlikely.

True, many men will come back with bacillary dysentery and amebic dysentery, but we have a high incidence of both these infections in the State at the present time. Although there may be some increase in infection of the members of the households to which these men return, our protection of water and milk supplies and methods of disposing of sewage should prevent any widespread outbreaks of these conditions, just as they have reduced in the past the incidence of typhoid fever and the other enteric infections. The rural areas with their admittedly poorer standards of environmental sanitation may show more of an increase than the urban areas, but just as typhoid disappeared in the rural areas as well as in the cities when the city water supplies were cleaned up, this increase in the rural incidence of enteric diseases should be a transitory phenomenon, if it appears at all.

With respect to those diseases in which there are intermediate hosts—I must confess that these concern me considerably more than the diseases that fall into the classification I have just discussed. Fortunately, we can check many of these diseases off the list for the simple reason that we simply do not have the necessary intermediate host in New York State. We probably should not be too sure about some of these diseases, however, since there is the possibility that the necessary host may be imported as well, just as the A. gambiae was accidentally brought, with devastating results, from Africa to South America, thereby greatly increasing the malaria hazard until through almost superhuman effort and at tremendous expense this vector was exterminated. Another possibility is that we may find that insects or other potential intermediate hosts which are already present in New York State are capable of transmitting the introduced disease, although in the past such insects were not known to be capable of so doing.

These are rather theoretic considerations, however, and rather than worry too much about them we probably should concentrate upon those tropical diseases for which we know we have the insect vector present and which at times in the past have been of great importance in this State. Malaria, of course, heads the list. This was formerly an extremely important communicable disease in New York State. In fact, only within the past twenty years or so has it essentially disappeared from the Hudson Valley as an endemic disease. We have plenty of anopheline mosquitoes and with the almost inevitable heavier seeding of them with malaria parasites, upon the return of members of our armed forces, it seems equally inevitable that there will be a rise in the prevalence of malaria among New York State residents who have not left home. This, however, should be a temporary rise, as there seems to be no reason to believe that the factors which were responsible for the decrease of malaria in this State in the past will not operate again to reduce the incidence. Some of these factors were concerned primarily with projects other than malaria control, such as land drainage for cultivation purposes, but many are the result of a deliberate antimosquito campaign, particularly in those counties in the vicinity of New York City. These campaigns are being carried on at present, and no doubt will be further intensified with the increased malarial threat.

The above remarks concerning malaria could be applied as well to yellow fever, although with the immunization of all members of the armed forces against yellow fever, and the very low population of Aedes aegypti mosquitoes in this State, there is little need to be concerned about a repetition of the yellow fever epidemics which occurred in this part of the country in the eighteenth and nineteenth centuries.

As to plague, this is not so remote a possibility as might appear on the surface. With the tremendously increased shipping to and from plague ports, and with the necessarily less careful supervision of ships returning from these ports, there is a substantial possibility that infected rat fleas may be introduced into New York City. Here again, however, we need to keep a proper perspective, since we have what appears to be a permanent focus of plague infection in the West in the form of plague in wild rodents. If plague should be introduced into this State, we should be able to control it well as far as cities are concerned through rat control procedures.

Lt. Col. Mackie's comments with regard to filariasis in South Carolina are of interest. Of equal interest to the presence of this focus, however, is the fact that it has continued to be localized in that area, in spite of the widespread prevalence of mosquitoes

which act as vectors. Therefore in this case there would appear to be some other factor involved in the spread besides the ready availability of the insect vector.

In conclusion, let me comment that as far as the tropical disease problem here is concerned one happy circumstance is the fact that in this State there are many thoroughly trained and experienced experts in tropical diseases, who may be called upon for advice if it is needed.

HOW LONG SHOULD A MAN WORK?

Somewhere there's a happy medium in the production period. If men work too long, they fatigue; and each task takes longer and longer until it's a losing battle. This, of course, does not even consider the poorer quality of work, the increased tendency toward accident or disease, and the steady rise in inefficiency.

On the other hand, if men do not work long enough, even though they do work efficiently, they can't turn out the maximum number of units. There's man-waste there—and again a losing battle. Somewhere between the two is the happy medium—the golden period where workers produce most without harming themselves or their product.

Now where is this period, important at any time in the smooth functioning of an industry, but especially important when a country is at war? A committee representing the War and Navy Departments, the Maritime Commission, the Public Health Service, the War Manpower Commission, the War Production Board, and the Commerce and Labor Departments studied the problem and here are its findings:

1. There should be a weekly day of rest. The Biblical injunction of one day's rest in seven seems to hold up after five thousand years. The seven-day work week for individuals is injurious to health, production, and morale. It slows down production because of the cumulative effects of fatigue when not broken by rest and relaxation. In fact, the workers take time off themselves. Too continuous work leads to increased absenteeism. Only in emergencies, and then for a limited time, should workers or supervisors (or doctors) forego their weekly day of rest.

2. There should be at least a thirty-minute meal period in midshift. Those working with toxic substances should be given sufficient time to cleanse their hands thoroughly before eating. (Physicians please note.) Also, there should be adequate food. Coffee and doughnuts for breakfast and a "coke" for lunch are not enough for a man or woman doing work.

3. The work day should be eight hours long, and the week six full days. Less than this makes for inadequate production. More than this, in time, results in impairing the health and efficiency of the workers and in decreasing the flow of production. Extra hours add little to output because the quality of work deteriorates not only during the extra hours but also during the regular working hours; absenteeism rises sharply and accidents and illness increase.

4. There should be vacations completely away from the job. These vacations should be so staggered as not to delay production and the period should be so balanced as to produce maximum benefit to the worker without too high a cost in productive hours lost.

Those are the recommendations, Doctor. How do they apply to your own practice and habits?—*Norman R. Goldsmith, M.D., in Pittsburgh Med. Bull.*

MOTHERS NOW ARE YOUNGER

According to the *Statistical Bulletin* of the Metropolitan Life Insurance Company, the burden of rearing the nation's children is being borne by very young women, and, at the same time, the proportion of young women within the reproductive ages is decreasing. In 1920 young women under 20 years of age contributed 8.6 per cent of the total births for the year. This percentage increased gradually to 11 per cent in 1935 and 1940. Women of ages 20 to 24 also contributed an increasing percentage of children during the two decades from 1920 to 1940, the figures mounting from 28.1 per cent at the beginning of this period to 31.3 per cent at the end.

However, the next age group, 25 to 29 years, presents a mixed picture. The relative contribution to total annual births borne by women of this age group at first fell from 27.9 per cent in 1920 to 26.1 per cent in 1930, but subsequently rose to 28.6 per cent in 1940. The net result was that, for this age group, as for those younger, the relative contribution at the end of the twenty-year period was greater than at its beginning.

In the case of women of ages 30 to 34, after some fluctuation, the percentage contribution to total annual births was *smaller* at the end of the two decades than at its beginning. In 1920 women of this age group bore 19 per cent of the children for the year, while in 1940 the figure fell to 17.7 per cent. A much more marked decrease is found among women of ages 35 or more who bore children. Whereas these women accounted for 16.4 per cent, or practically one-sixth of the births in 1920, by 1940 the figure for this age group fell to 11.4 per cent, or about one-ninth of the total.—*Medical Record*

NEW DEVELOPMENTS IN INFANTILE PARALYSIS

DON W. GUDAKUNST, M.D., New York City

THE past few years have brought to us more knowledge of poliomyelitis than all the previous generations in which this disease has been known to man. The common concept of poliomyelitis was that it was a virus disease, capable of using the olfactory nerve as its portal of entry to the human central nervous system, and that it produced death of anterior horn cells of the cord with resultant paralysis. These were true observations, as far as they went, but they were also dangerous half-truths, for they failed to take into consideration other important factors. There was little appreciation of the extensive pathologic changes and consequently but a poor understanding of the complete symptomatology.

The virus is an obligatory neural parasite. While it can retain its infectious and invasive powers for extremely long periods of time under the most varied and apparently adverse circumstances, it cannot multiply save when it draws upon the substance of particular nerve cells for its metabolic requirements. Although it has been found in the blood stream, it apparently cannot reproduce there, and when it is present it is there only as an inactive agent. The so-called "general systemic" stage of the disease is not due to such a blood stream infection but is dependent upon a much more complicated mechanism resulting from central and brain nerve cell invasion.

The normal and usual method of travel of the virus throughout the body is reported to be by the pathways provided by the nerves. This is a neuro- or neuronotrophic virus. It leaves no demonstrable histologic change as it travels over or through the nerve fibers, yet its spread by way of neurons is dependent on healthy normal fibers and nerve cells. For example, it cannot progress in nerve tissue that has not fully regenerated after traumatic changes. The rate of the progression of the virus in peripheral nerves to the central nervous system has been calculated by Howe and Bodian[1] to be at the rate of 2.4 mm. per hour in the experimental animal. Such travel occurred in both the motor and the sensory fibers.

With travel of the virus within the body being along nerve fibers, the portal of entry becomes comparatively important in determining which portion of the central nervous system will be first invaded and consequently what train of symptoms are to develop. While the olfactory route is possible and while the olfactory pathway and the olfactory bulb are quite susceptible to virus invasion, the laboratory evidence fails to show that this is a common route in man. In the complete and careful examination of human autopsy material, Kessel[2] and his associates found but one olfactory bulb involved in 11 cases. Similarly, other workers—Sabin and Ward,[3] Howe and Bodian,[1] Swan,[4] and others[5]—have repeatedly presented findings that emphasize the fact that invasion by the olfactory pathway is a rare occurrence in human beings. Yet it has been only a few short years since the attention of much of the medical profession was focused on attempts to prevent poliomyelitis by blocking this single portal of entrance.

In the experimental animal, clinical disease can be produced by many portals. Although direct inoculation into the brain substances is a commonly used method, this is by no means the only portal. This method has been used because of the relative resistance of the experimental animals and because of the lack of sufficient concentration and purification of virus from the test material. In the relatively more susceptible animal the gastrointestinal tract offers a certain method of infection, as do the intracutaneous and subcutaneous routes. Direct inoculation into peripheral nerves produces central infections. Faber and Silverberg[6] have reported infection in monkeys by inhalation. The nasal and peritoneal routes are commonly utilized. Any method that allows the virus to come in contact with nerve tissue offers a suitable means of infection in the susceptible animal. There is no reason to think that this does not hold true in man, with a vast amount of evidence pointing to the fact that the gut is the common gateway.

Former teachings were to the effect that the virus was eliminated from the nasal pharynx and upper respiratory passages. This, too, is only a small part of the story. Repeated observations on the part of many workers fail to show the virus in the nasal pharyngeal secretions or washings, except on rare occasions and then only during the early course of the disease. There is no demonstrable centrifugal spread of the virus from the central nervous system to the nasal and olfactory passages. Kling, Pettersson, and Wernstedt[7] in 1912 reported the recovery of virus from human stools, but it remained for Trask and

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943, by John L. Lavan, M.D., Dr. P.H., Director of Research, The National Foundation for Infantile Paralysis, Inc.

Medical Director, the National Foundation for Infantile Paralysis, Inc.

Paul[5] and later workers to show that this is not merely an occasional occurrence but that it is regular. Virus can be demonstrated with present-day methods in the stools of all patients and frequently in the stools of many contacts. That such elimination is not a transient phenomenon but occurs over periods of weeks and months has been shown by Piszczek[9,10] and Zichis.[9]

These are findings that depend to a large extent on the more recently developed and more nearly exact methods of detection and study of the poliomyelitis virus. Appreciation of them gives a much better basis for understanding infantile paralysis and has a direct bearing on the management of the case, but the methods of examining pathologic material from both human and experimental sources have not changed greatly during the past few decades. The impression is common with many clinicians that this disease is one which primarily, if not almost exclusively, affects the anterior horn cells of the spinal cord, producing its symptoms by death of these cells or by damage from edema and hemorrhage into the adjacent cord. Undoubtedly the very name of "acute anterior poliomyelitis" given to this form of paralyzing infection has tended to further these misconceptions of a sharply limited pathology. Careful studies of many hundreds of animals infected by routes other than direct intracerebral inoculation show that the cord may or may not be involved, while the brain always is. A similar condition has been found in a few human patients who died of intercurrent causes, either in a mild infection or before there had been time for extensive spread. The anterior gray part may or may not be involved when lesions are present in the cord. The posterior columns, the pyramidal tracts, the lateral and the intermediate zone or internuncial cells, the intervertebral ganglia[11] or dorsal roots all may commonly show unmistakable signs of virus invasion and damage with no correlation between the severity or extent of lesions in these areas and those in the anterior horn cells.

In all diagnosable cases of poliomyelitis, with the possible exception of early nonparalytic types with complete, spontaneous arrest of symptoms, there is an encephalitis with involvement of parts of the motor cortex. There is commonly an accompanying meningitis which is usually of a mild nature and is probably secondary to the deeper involvement. This pathology may or may not be accompanied by clinical symptoms and there may or may not be further pathologic changes in the cord. The medulla, midbrain, and thalamus are routinely involved in both the experimental animal infected by the gastrointestinal or pharyngeal routes and in man as evidenced by the study of pathologic changes[1] and by recovery of the virus.[3] These may be the only areas that show such changes.

The interpretation of clinical symptoms on the basis of pathologic findings is not easy. Examination of autopsy material commonly reveals extensive pathology totally unsuspected and unpredicted by clinical symptoms alone. And, likewise, the clinical manifestations at times are apparently out of all proportion to the severity of the manifest lesions present in the anterior horn cells of the corresponding cord-segment. The picture is indeed a complicated one. With extensive involvement of both sensory and motor cells over large areas of the central nervous system, and with the changes varying from slight reversible reactions to complete destruction of many cells, it is to be expected that there would not be a single clinical picture. It is certain that the simple concept of paralysis as the sole or main symptom is no longer reasonable. That paralysis can and does occur is certain, but it is equally certain that it is but an inconstant part of a complicated train of symptoms. With such massive and extensive involvement, it is apparent that pain, hyperirritability, and increased muscle reaction to stretch reflex (sometimes referred to as "spasm") and incoordination of muscle action all could be expected. It is also apparent that inability to perform voluntary motion of a muscle could be due to many neural mechanisms other than death of anterior horn cells. Disturbances at many levels in physical continuity and function of motor pathways with changes in nuclei and in communicating and connecting tracts of the central nervous system could well cause a pseudo- or temporary paralysis without significant damage in the corresponding anterior horn cells. It is not necessary to hypothecate ephemeral changes in anterior horn cells when demonstrable lesions occur at other key points of the neuromuscular system.

With these thoughts in mind, it is apparent that the medical profession was more than ready for some change in the system of therapy, therapy aimed at securing "rest" of damaged anterior horn cells through lessening of motion of the extremity and at providing protection of a weakened muscle from the pull of a strong, unaffected opposing muscle, with the hope of preventing future contractures and fibrotic changes.

There is no real evidence that either of these objectives was accomplished in the majority of cases. Certainly there is no physiologic evidence that muscular rest alters the rate of degeneration of infected or damaged anterior horn cells, nor is there satisfactory evidence that protracted immobilization prevents contractures and deformities.

In 1940, Elizabeth Kenny, an Australian nurse, came to this country and found an opportunity to demonstrate her methods and form of treatment at the University of Minnesota in Minneapolis. Funds were made available to that university by the National Foundation for Infantile Paralysis for the purpose of studying and evaluating her claims and contentions. A series of controlled cases was planned, the work being under the supervision of orthopaedic surgeons and physicians in physical medicine. Cases were admitted for trial. Publicity was carefully avoided at that university but the controlled experiment was not possible, for with the treatment of the first few cases the parents and the physicians of the community demanded the Kenny method. The results of her methods were spectacularly different. It is to be emphasized that until the present time all evaluation of these results has been based on only clinical impressions. Alternate cases for control purposes could not and probably can never be arranged. The value of the clinical impressions was fortified in so far as possible by obtaining the opinions of recognized and outstanding authorities in medical practice. Other studies, based on more exact physiologic evaluation of clinical changes, are currently being conducted. These studies must of necessity be both tedious and time-consuming. In most instances findings are as yet too fragmentary to be reported.

At about the end of the first year of study the National Foundation received a report from the University of Minnesota. This report, with some modifications and deletions, was carried in the *Journal of the American Medical Association* in June, 1941. Additional cases were admitted to the University Hospital and the Minneapolis General Hospital. Further observations were made. In December, 1941, a second report was rendered by the University to the National Foundation, in which it was stated in substance that the treatment did relieve the patient of pain, that there was apparently less stiffness, and that there was no evidence of contractures in the cases treated by Sister Kenny, up to that date. This report was most carefully considered by the National Foundation officials and advisory committee members. As a result, it was recommended that instruction in the method of treatment and the concept upon which it was based be made available to the medical and public health authorities of this country for their use, if they so desired. No other claims were made by the National Foundation with respect to this treatment.

Kenny has developed a method of treatment based on a concept of poliomyelitis that differs from the former one of flaccid paralysis as the predominant symptom. No attempt has been made to pass on the merits of her ideas; they are presented for clarification only. To her, "spasm" or increase in tonus and irritability of voluntary muscle is the prominent and important symptom. This does not preclude the possibility of true paralysis occurring as a result of massive destruction of anterior horn cells, but, according to her observations, this is a comparatively rare event, being present in not over 10 to 15 per cent of the patients admitted to any hospital for early medical care. In the usual case the spasm is directly or indirectly responsible for most of the symptoms. The early pain and the later tenderness on pressure and action, as well as still later contractures, are due to this spasm. Furthermore, the inability of a certain muscle to contract and to produce useful motion may be due to the pull of the opposing muscle or muscle groups acting as a simple brake, or because the muscle is pulled out of its normal resting stage into an extended position from which it is not capable of producing a contraction. Much that has been called paralysis and was thought to be due to anterior horn-cell damage is, according to Kenny, not flaccid paralysis but spasm in the opposing muscle, due, probably, to lesions at some level higher than the anterior horn cells, or due to other changes in the neuromuscular structure and function.

The treatment which Kenny has advanced for these conditions is aimed first at overcoming pain and spasm and second at providing early muscle training to re-establish muscle function and motor pathways. Both these objectives involve technics that have tended to set this special treatment aside as a "method." Actually, there is little that is new or different in the modalities employed. The method of application, the time of application, and particularly their purposes are different.

The application of heat by use of compresses at unusually high temperatures does quickly relieve the common symptom of pain found early in many severe poliomyelitis infections. Evidences of disturbance of circulation rapidly disappear, as do changes in temperature of the involved parts. There are beneficent effects in addition to the primary purpose of providing relaxation of spasm by reflex action.

As soon as the pain and tenderness subside and as soon as motion can be performed without discomfort, the affected parts are moved through their utilizable arc of motion. Without attempting to give the details of the work in physical therapy carried out by Kenny, suffice it to say that the aim is not that of restoring strength but rather of securing a rhythmic and coordinated action of all muscles concerned with any motion.

Weakened, "incoordinated," or "alienated" muscles (to use her term) are stimulated and directed by individual attention to resume their correct function, normal in point of time and direction of action. Other muscles not involved or involved to a lesser degree are discouraged from assuming any abnormal action as the result of the patient's willful or unconscious effort to effect a desired motion.

As a result of the combination of heat, regulated exercise, the direction of motor impulses, and the absences of long periods of immobilization, patients under the Kenny form of treatment show many desirable benefits. Today there is much that is not fully understood about this or other methods of treatment. There is much yet to be found out. There is much that must be done to lessen the time and the amount of work now required to apply successfully the Kenny method to any large group of patients.

Alternate case studies have not been possible, but those who know her work best want to see its benefits extended. While there is today a lack of scientifically controlled evidence both with respect to clinical cases and as collected in the laboratory, there are few who will deny that Elizabeth Kenny has made a great contribution to the control of the end results of poliomyelitis. There has been interjected for both patient and physician alike a new hope for lessening the crippling aftereffects; there has been provided a new stimulus to those who work in research. A new line of study has been emphasized as important

CONTINUOUS CAUDAL ANESTHESIA HAS WAR USE

The new safe method of making childbirth painless and comfortable, called continuous caudal anesthesia, may prove a great boon to the war wounded, it appears from a report by Dr James L Southworth, Dr. Waldo B Edwards, and Dr. Robert A Hingson, of the U S. Public Health Service

The new anesthesia has now been used in 255 cases in general surgery with only three failures, the doctors report The cases included operations for femoral and inguinal hernia, cesarean delivery of a baby; setting of broken bones, other orthopaedic operations, and amputations of legs and feet; and surgical treatment of varicose veins. It also shows promise as a method of treating thrombophlebitis in the legs.

"It would seem," the doctors state, "that this method is adaptable for use in the treatment of casualties both in civilian and military practice where it would be desirable to have a safe, prolonged analgesia during the transportation and the physical and roentgenologic examinations of the injured"

One anesthetist with several trained corpsmen or medical attendants could handle a large number of patients at one time, they point out. It might be possible to give this anesthetic to some of the war wounded on the field and transport them painlessly to a base for treatment, thus perhaps reducing the instances of shock. The method might also be valuable in preventing the delayed shock condition usually referred to as "crush syndrome."

The new anesthetic method consists of continuous injection near the base of the spine of a pain-killing chemical, metycaine. The drug temporarily blocks the nerve pathways for pain below the level of the umbilicus but does not cause unconsciousness Its chief disadvantage for surgical operations is the time consumed—thirty to forty minutes—to give the anesthetic and allow it to become complete A skilled anesthetist, however, can have the patient ready for certain types of operations in ten minutes.—*Science News Letter*

TUBERCULOSIS AND THE POOR

We must keep well in mind that tuberculosis is a poor man's disease. It kills seven times as many per hundred thousand among unskilled workers as among the higher paid individuals. It strikes those least prepared to take the blow. That fact in itself is sufficient to make it imperative that the cost come out of sources other than the victims' meager income

If we are going to finance the war (against tuberculosis) out of the pockets of those found to be suffering from the disease, we may as well hoist the white flag. The war cannot be won that way. The public health is the public trust and responsibility and doubly so when the danger comes from a communicable disease.—*Matthew Woll, in Penna's Health*

VAGINAL ANTISEPSIS DURING LABOR*

HARRY W. MAYES, A. M., M.D., F.A.C.S., Brooklyn

AT THE present time great differences of opinion exist among obstetricians as to the value of using any antiseptic solution in the birth canal during labor and at the time of delivery. This report was undertaken in order to determine the opinions of obstetricians and to present a summary of the findings from a group of hospitals so that a clearer picture may be given of the current status and degree of acceptance which this procedure has achieved.

Survey of Diplomates of the American Board

A survey of Diplomates of the American Board of Obstetrics and Gynecology is shown in Table 1. Of the 848 men who replied, 517, or 60.9 per cent, reported that they use vaginal instillations during labor. Of this 60.9 per cent, 248 (29.2 per cent) of the entire group used them routinely and 269 (31.7 per cent) occasionally. Thirty-six physicians did not report on the use of the procedure in labor since they practice only gynecology. Two hundred and ninety-six (34.9 per cent) used the technic routinely before doing a cesarean section, 29 (3.4 per cent) used it occasionally, and 424 (50 per cent), not at all. Ninety-nine (11.6 per cent) did not reply.

Inquiring further in order to determine whether and how often vaginal antiseptics were used before gynecologic operations, we found that 442 of the 848 physicians prepared the vagina before doing a hysterectomy, 342 out of 602 before doing a dilatation and curettage (this question was not included in the first cards sent out), but only 348 of the 848 prepared the vagina in treating abortions. The large number of women who develop infection following abortion and miscarriage may be accounted for in part by the fact that fewer than half of their physicians use vaginal antiseptics in these cases.

The number of maternal deaths and deaths from sepsis was not reported in this survey.

There were 305 physicians who expressed favorable opinions regarding the use of vaginal antiseptics during labor. Seven reported having used vaginal instillations for from ten to fifteen years. Many physicians stressed the careful use of vaginal instillations; others reported that the technic was indicated in long labors and in operative deliveries.

In evaluating the expression of opinion of the Diplomates, it seems only fair to take into consideration the experience which the individual member has had with the use of vaginal instillations. Those who use instillations routinely should be better judges than those who use them only occasionally or not at all. There were 52 Diplomates who opposed instillations. This is 6 per cent of those who replied to the survey, and since these men state that they have never used the technic, their opinions are based on other factors. Thirteen thought their records were good enough without the protection offered by the use of vaginal instillations.

Concerning the antiseptics used and the number of cases reported (Table 2), 180 of the 517 obstetricians who used vaginal instillations in labor used mercurochrome and reported 121,675 deliveries; 142 used merthiolate and reported 44,000 deliveries. There were 24 different solutions used—some used more than one solution—and a total of 224,575 deliveries. Mercurochrome was the principal antiseptic used when vaginal instillations were first introduced, and although many of the reports have indicated a change to other solutions, it still remains the most popular.

During the last eighteen years at the Methodist Hospital we have been using vaginal instillations of mercurochrome as routine during labor and at the time of delivery. We have had 25,000 vaginal deliveries with but two deaths from infection, and there have been no such deaths in the last 12,000 vaginal deliveries.

We are convinced that the instillations were definitely responsible for reducing our morbidity and mortality from puerperal infection, but there are still many physicians who are either undecided as to the value of the method or who are definitely opposed to it. In order to present a larger series of cases and to bring further evidence to bear on the subject, I have contacted other hospitals whose statistics are here reviewed.

Hospital Survey

Out of 41 hospitals reporting, 14 used instillations routinely, 16 occasionally, and 11 not at all. Of the 30 that employed the technic, 18 used mercurochrome, 7 used merthiolate, and 5 used other solutions. Of these 30 hospitals, rectal examinations were made routinely in 7, rectal and vaginal examinations occasionally or when indicated in 14, and both rectal and vaginal in 6.

* Survey of 848 Diplomates of the American Board of Obstetrics and Gynecology, and a study of 236,295 hospital deliveries following its use.

Attending Obstetrician and Gynecologist of the Methodist Hospital, Brooklyn.

TABLE 1.—SURVEY OF DIPLOMATES OF THE AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY*

Use Vaginal Instillations During Labor		Use Vaginal Instillations Before Cesarean Section	
Use routinely	248	Use routinely	296
Use occasionally	269	Use occasionally	29
Use no instillations	295	Use no instillations	424

Antiseptics Used	Physicians	Cases Reported
Mercurochrome	180	121,675
Merthiolate	142	44,000
Acriflavine in glycerin	44	25,700
Zephiran	22	3,200
Metaphen	19	10,000
Mercresin	16	17,000
Other solutions	...	3,000
Total		224,575

Three did not report. Several solutions were used in the preparation of the perineum for delivery. Of these, 13 were mercurochrome, 7 merthiolate, 4 mercresin, and 2 lysol.

There were (Table 3) 133,150 deliveries following the use of mercurochrome as a vaginal antiseptic, both routinely and occasionally, with a death rate due to sepsis of 0.33 per 1,000 deliveries. Following the routine use of mercurochrome, there were 63,751 deliveries with a rate of 0.31. With mercurochrome used only occasionally, there were 69,399 deliveries with a rate of 0.34 deaths per 1,000. If we omit the records from one hospital where mercurochrome is used very infrequently, there would be only 8 deaths from sepsis for 51,100 deliveries where mercurochrome was used occasionally. Three of these followed cesarean sections.

Following the use of other antiseptics, there was a total of 103,145 deliveries with a death rate from sepsis of 0.46. In 72,900 of these deliveries, the instillations were used as routine with a rate of 0.50, and in 30,245 they were used occasionally with a rate of 0.36. Thirty-four of the 37 deaths in hospitals using other antiseptics routinely occurred in two hospitals. Omitting their statistics, there were 23,794 deliveries following the routine use of an antiseptic other than mercurochrome with but 3 deaths from sepsis.

Among the 11 hospitals which did not use vaginal antiseptics, 5 reported 45,457 deliveries with 48 deaths from puerperal infection, a little over one septic death for each 1,000 deliveries.

In the 30 hospitals using instillations either routinely or occasionally, the death rate for cesareans where instillations were used was 4.6 per 1,000. In the 11 hospitals not using instillations it was 12 per 1,000. There were 2,475 cesarean sections following the mercurochrome technic with only 8 deaths from infection, a rate of 3.2 per 1,000.

Reports from abortions are not so encouraging. This is probably due to the fact that though patients are instilled for labor, similar precaution against infection is omitted for abortions. In the 30 hospitals that use instillations for labor, there were 11,566 cases of abortion in which vaginal antiseptics may or may not have been used. A percentage of 76.3 of the deaths were due to infection, a rate of 6.6 per 1,000 cases. In the hospitals that do not use vaginal antiseptics for labor, there were 6,787 abortions in which instillations were not used, with 86 per cent of the deaths due to sepsis, a rate of 7.9 per 1,000. We have had 690 abortions at the Methodist Hospital without a death from sepsis. The patients are instilled as though they were in labor.

The increased interest and improvement in technic in the use of vaginal antiseptics is shown by the fact that in these 30 hospitals during the last three years (1939, 1940, 1941) there have been 95,890 deliveries with vaginal antiseptics used routinely or occasionally and only 12 deaths resulting from puerperal infection. In 52,746 deliveries mercurochrome was used, with 5

U S A. (1940)	2,360,399		2,292	0 90								

deaths from sepsis; in 43,144 deliveries where other solutions were used, 7 deaths occurred. During the same period, there were 13,424 cases in which no instillations were used, with 6 deaths from sepsis.

Conclusions

The prophylactic use of a vaginal antiseptic during labor and at the time of delivery is no longer in the experimental stage. This is indicated by the fact that 517 out of 848 Diplomates of the American Board of Obstetrics and Gynecology use vaginal antiseptics during labor, and that during the last three years (1939, 1940, 1941) 95,890 patients covered in a hospital survey have been delivered following the use of vaginal antiseptics with only 12 deaths from sepsis. Of these deliveries, the mercurochrome technic was used in 52,746, either routinely or occasionally, with but 5 deaths from infection.

ALLERGIC TUBERCULOSIS IMMUNITY

Widely accepted views as to the relationship between [illegible] in tuberculosis are challenged [illegible] Kelly of the Detroit Tuberculosis Sanatorium. In a recent summary Rich concluded that allergy is not a necessary accompaniment of an effective immunity in any infectious disease. This conclusion was based largely on experiments which indicated that allergic guinea pigs that are given desensitizing doses of tuberculin are able to withstand subsequent infection with highly virulent strains of tubercle bacilli as well as control guinea pigs left in their original hypersensitive state. This result is of practical clinical interest, since it suggests that tuberculin therapy is without deleterious effects.

Subsequently, Willis questioned the experimental basis for this conclusion, since he found that there was but slight difference between allergic and desensitized guinea pigs if they were given massive test doses of highly virulent tubercle bacilli but that the results were quite different with smaller or less virulent doses. With doses that allow the injected animals to remain alive for at least six months, a 100 per cent mortality of the tuberculin-desensitized animals took place long before all non-desensitized controls had died. Moreover, in the desensitized animals the lungs were almost completely hepatized by tuberculous pneumonia, with little or no involvement of the liver or the spleen. In the allergic controls the pulmonary involvement was minimal, the spleen being the organ showing the maximum predilection to the disease. Lack of acquired allergy was apparently responsible for the free and unrestrained growth of tubercle bacilli in the desensitized lungs.

During the past three years 218 normal guinea pigs have been infected subcutaneously with fatal doses of virulent human tubercle bacilli in the Detroit Laboratory and tested quantitatively for skin sensitivity throughout the course of the disease. In all cases the acquired skin sensitivity increased to a maximum in about four to five weeks. After this the animals could be divided into two groups. In one group the skin sensitivity decreases rapidly after the fifth week, the animals becoming desensitized by about the twelfth week, which spontaneous desensitization was invariably followed by death. On necropsy, extensive pulmonary involvement was noted, with enormous numbers of tubercle bacilli in the lungs. In the other group the acquired skin sensitivity was not decreased but increased slightly above the five-week level. These durallergic animals remained alive well beyond the fourteenth week and on etherization showed but few acid-fast bacilli in pulmonary sections or smears.

From such data Woodruff and Kelly conclude that a quantitative relationship between skin sensitivity and pulmonary resistance to tuberculosis exists, nonallergic or spontaneously desensitized pulmonary tissues favoring a profuse local proliferation of the tubercle bacilli. Spontaneous desensitization is demonstrated also in human tuberculous patients—*J.A.M.A.*

WHAT DOES THE SURGEON EXPECT OF HIS HOSPITAL?

Surely, the surgeon should be entitled to a hospital with more than merely a well-planned operating room, able assistants, a capable laboratory. Dr. Walter Alvarez a few years ago delivered a talk on "The Pride of the Physician in His Profession." Basically, there must also be a pride of the surgeon in his hospital if he would be happy. A pride not alone in its appearance, its equipment, and its bed capacity, but in its moral standards, its position in the community, the capacity not of its beds but of its heart. And the heart of the hospital is the "humanitarian spirit in which the best care of the patient is always the primary consideration."

I should expect my hospital, then, to be not only a place of work but a place to serve—a place to work for the betterment of my private patients, but no less one in which I have a ward service where I am free to serve for the joy of working and the accrual of knowledge. I would wish for an opportunity to teach the interns and nurses some of the truths as I have learned them and would expect their cooperative help in return. "Tell it not in Gath," but, last, I would pray for a board of directors mindful of its duty to the community and appreciative of my labors, which would uphold my arms and offer every opportunity within its power to further the art of surgery.—*Paul S. Lowenstein, M.D., in Modern Hospital*

THE CARE OF SOFT TISSUE INJURIES

FORREST YOUNG, M.D., Rochester, New York

THE soft tissues" is a term which has by common usage come to mean all those structures external to the skeleton and the internal organs. These tissues, because of their superficial location, are injured more frequently than any other. Many such injuries are of such minor character that the patient attends to them himself; some are so serious that they may permanently destroy important functions.

Since earliest times the treatment of wounds and the factors which influence their healing have been of primary interest to all surgeons. This interest is, of course, increased during times of war when great numbers of soft tissue injuries must be treated, at times under rather adverse conditions, and it is in such times that improvement in the methods of treating wounds may well be expected to occur. However, in order that we may be capable of critically judging new proposals and technics for the treatment of wounds, it is necessary that we have a thorough understanding of the fundamentals of wound healing. There are many factors of a general rather than a local nature which influence wound healing. Some of these are age, diet, local infection, and possibly hormones. It is well known that wounds heal more rapidly in the young than in the aged. There is evidence that avitaminosis and hypoproteinemia slow wound healing. Distant infection may at times cause infection in a wound that is quite remote. But these general factors are of no practical importance in the treatment of accidental wounds in healthy patients.

The mechanism of wound healing is, in essence, the same in traumatic wounds as it is in those made with surgical intent. In the surgical wound the surgeon is able to eliminate or at least to minimize some of those factors that are unfavorable to wound healing and to decrease the extent of bacterial contamination. Wound infection has always been considered the most important factor in causing delay in wound healing, but one must remember that the pathologic process of repair and the local response to infection are identical and are both recognized under the term "inflammation." It is well known that some infected wounds heal as rapidly as similar clean wounds do. After the excision of a carbuncle, the wound may heal as rapidly as a clean wound of like extent does. Many surgeons have concluded, from their own observations that simple surface infection does not primarily deter wound healing, and it is this observation that has undoubtedly caused a certain school of surgeons to become antiseptic nihilists. However, it is not primarily because of the effect on the local wounds that infection is to be feared but rather because of infection generally. Anaerobic infection, if locked in a closed wound, may even cause loss of life, and pyogenic infection may result in widespread cellulitis or septicemia.

There are certain local mechanical factors more or less under the direct control of the surgeon which can in themselves delay wound healing even in the absence of infection. Moreover, it is known that inattention to these various factors predisposes to infection, with its effect on wound healing. These adverse factors are:

(1) Foreign bodies. Not all foreign bodies will prevent wound healing, but large or numerous foreign particles near the surface will prevent healing until they are either absorbed or cast off.

(2) Devitalized tissue acts as a foreign body until it is absorbed or sequestrated, and in the depths of a wound it is a nidus for infection.

(3) Trauma will delay wound healing. This is well illustrated in wounds of moving parts which are not adequately sutured or splintered. Surface healing is often interfered with by the trauma caused by removing dressings which are adherent and thus disturbing regenerating epithelium.

(4) Dead space, even though uninfected, will increase the volume of a wound and thus increase the time required for healing.

(5) Tension. Any wound closed under tension is predisposed to infection because of the damage to blood supply and the subsequent necrosis which may occur.

(6) The accumulation of exudate under tension after the wound is closed, such as hematomas, will in the same manner as closure under tension delay wound healing by decrease in local blood supply. The necrosis which may result tends to cause infection. It would seem, then, that the problem of wound healing is primarily a mechanical one, for not only does inattention to these various mechanical factors delay healing but if they are not adequately provided for, infection is invited.

Promptness of wound healing is desirable, because not only is the period of illness and disability decreased by a wound that heals promptly but also a wound which heals by first intention

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

From the Department of Surgery, University of Rochester School of Medicine and Dentistry, Rochester, New York.

produces much less disabling scar tissue than does a wound that heals by the slow process of second intention. The ideal would be to convert every accidental soft tissue injury into a wound similar to that made with surgical intent. This, of course, is not possible in all instances, but it should be the ideal to strive for, and in many instances what appears to be a wound which must be left open to heal can be, by careful surgery based on the factors above, converted into a wound which will heal primarily. It cannot be overemphasized that this objective can be attained only by meticulous attention to all details of mechanical care of the wound, for, if any one factor is not accounted for, disaster may occur, either as a systemic infection which may endanger life or as a local infection which will seriously prolong healing.

The treatment of soft tissue injuries should then be directed objectively toward the solution of the mechanical problems just enumerated. Such treatment naturally falls under well-defined headings directed toward the prevention of these unfavorable factors.

(1) Cleansing. All soft tissue injuries should be thoroughly cleansed. There is no antiseptic application that takes the place of thorough mechanical cleansing. The wound should be thoroughly washed under aseptic conditions. The best method of cleansing is to wash the wound and surrounding skin thoroughly with a mild soap and sterile saline. A heavy lather should be worked up and the wound thoroughly washed for a period of at least ten minutes. The lather can be increased by the use of half-and-half hydrogen peroxide, 1 per cent, with soap. The wound should not be scrubbed with a brush since this increases the trauma, but soft gauze should be used. The objective of the soap and saline scrub is to remove all foreign bodies as well as all torn off tissue. After the soap washing, the wound should be irrigated thoroughly with a running stream of saline. Following this, a meticulous inspection of the wound for foreign bodies is made. No antiseptic is applied after washing, for there is no known application which does not damage, to a certain extent, the exposed raw tissue.

(2) The removal of devitalized tissue. "Débridement" is a word which is glibly used but rarely practiced in the true sense. Too often it is taken to mean a haphazard excision of ragged skin edges and a clipping away of obviously dead tissue. Débridement is intended to convert a contaminated wound into a surgical one. This cannot be accomplished in every wound because of the involvement of vital structures, but in certain locations it can be practiced. After thorough cleansing, the soft tissue injury is packed with sterile gauze. A circumferential incision is then made around the wound and the entire contaminated wound lifted out as a core. This is done without penetrating into the accidental wound cavity and the resulting wound is one which as nearly as possible approximates a surgically made incision.

(3) Hemostasis. Control of bleeding was probably the first principle of wound care practiced by surgeons. In wound care hemostasis is an important factor in bringing about uninterrupted healing. All bleeding points must be clamped and ligated with fine suture material. There are some surgeons who believe that nonabsorbable material can be safely used in contaminated wounds, and in certain instances we accept this as being practical, but if there is any doubt as to the cleanliness of the wound, then catgut ligature material is favored. In either instance a minimum of ligatures should be used, for they themselves act as foreign bodies. For this reason only the finest catgut is used, in sizes three to five zero. Capillary ooze should be controlled before the wound is closed. This can be done efficiently by the application of warm packs held under some pressure against the wound surfaces. Hemostasis in all traumatic wounds should be so complete that drains are unnecessary.

(4) Closure. In these days of military surgery the closure of soft tissue injuries is a debatable point. There is, I believe, no question that if the wound can be closed with safety, closing it is better practice than leaving it open to granulate. The word "safety" is used advisedly because there are certain wounds in which closure cannot be done safely since to do so would violate the principles that we have already enumerated. The wound in which there is such extensive injury that débridement cannot be satisfactorily carried out, the wound in which there is such great loss of tissue that tension would occur if it were closed, the wound that is attended to later than six hours after its inception, and the wound, perhaps, that is attended to by a person without sufficient experience to have sound surgical judgment are safer left open. If, in the judgment of the surgeon, the wound can be closed, the closure must not violate the fundamental mechanical factors. The suturing of the wound should be carried out with fine interrupted stitches. Continuous sutures introduce more foreign material into the wound than is necessary and all running stitches tend to constrict the blood supply so that there is a moderate amount of tissue devitalization. Suture material should be of small size, for it has been amply demonstrated that the tensile strength of the sutured tissues is not so great as the strength of the larger sizes of catgut

or the heavier strands of nonabsorbable material. Some soft tissue injuries received under clean circumstances and by a sharp cutting force, such as that of broken glass, can be safely sutured with nonabsorbable interrupted sutures of either silk or cotton. More extensive wounds with contusion of edges and partial devitalization of surrounding tissues received under dirty conditions are more safely sutured with very fine catgut. In any event, the closure of the skin edges should be carried out with interrupted stitches of nonabsorbable material. In most locations either silk or cotton can be used for this purpose, but about the face, where scarring must be kept at a minimum, horsehair is a preferable material because it has so little tensile strength that it cannot be tied under tension and because it is impervious to moisture absorption.

(5) Immobilization. Soft tissue injuries of any extent heal more promptly and with less discomfort to the patient if the part is immobilized. This fact is not well appreciated, but it is true that immobilization of soft-part injuries is just as valuable as the immobilization of wounded bones. If the injury is on an extremity, the joints above and below the injury should be immobilized by plaster splints. In addition, the dressings should be of the compression type. This dressing consists of several layers of sterile surgical gauze over which either sea sponges or mechanics waste is applied in order that the dressing will be quite thick. A gauze roll or elastic type of bandage, such as ace bandage or stockinette, is then used to supply moderate pressure over the part. Compression is likewise a principle that is not well appreciated in the treatment of soft part injuries. It aids in fulfilling many of the criteria already mentioned. It tends to prevent capillary ooze and hematoma formation, and to a certain extent it provides immobilization. It prevents lymphedema and the accumulation of exudates in the wound and, if there are partly avulsed areas of the skin and subcutaneous tissues that have questionable circulation, compression prevents venous accumulation of blood and subsequent necrosis.

(6) Infrequent dressings. If the patient is comfortable and if there are no signs of infection, such as mounting fever, leukocytosis, drainage, or odor, then the immobilizing dressing should be disturbed infrequently. Frequent change of dressing traumatizes the healing wound, disturbs immobilization, and affords a renewed opportunity for the introduction of infection. The healing period of a soft tissue wound is, roughly, two weeks and, unless there are signs pointing to suppuration of the wound, there is no need to change the dressing originally applied during this period.

We shall now consider the various types of soft tissue injuries and briefly outline the treatment based upon the surgical principles that we have been discussing.

Abrasion.—This is the simplest of soft tissue injury. The injury may be extensive, but it is never deep. There are always sufficient epithelial remnants left to heal the area completely. Treatment consists of thorough soap-and-water cleansing under aseptic conditions. Particular attention must be paid to this step if the abrasion has occurred where carbon particles might be present. Such injuries are those received by a fireman around a furnace where there is soot, a roofer working on an asphalt roof, or a mechanic working about a greasy machine. Abrasions received under such conditions are apt to have carbon particles ground into them and, if these are not entirely removed, the abrasion when healed will be blue in color and will resemble a tattoo mark. These are particularly disfiguring when they occur about the face. At times these particles are ground so deeply into the derma that they can be removed only by actual shaving of the deeper tissues. Cleansing is followed by thorough irrigation with sterile saline solution. The wound is then dried with sterile gauze or with a stream of warm air from a dryer such as those used by hairdressers. One thickness of fine meshed vaselinized gauze is applied smoothly over the abraded areas and a compression dressing and an immobilizing splint are applied. If this dressing is disturbed during the first week, it will be noted that its removal causes bleeding due to the tearing away of thin regenerating epithelium. If there are no signs of infection, it is best to leave such a dressing undisturbed for from ten days to two weeks.

Contusions.—A contusion is an injury of the soft parts by blunt force of sufficient severity to injure the tissues deeply and yet not break the skin. In such injuries large hematomas may develop because of rupture of veins in the deeper tissues. As this pool of blood forms, tension occurs and may proceed to such a point that there is diminution in blood supply of the overlying skin. This may progress to actual necrosis with loss. If the patient is seen immediately after a severe contusion, hematoma formation can often be prevented by the simple application of an efficient compression dressing. If a large hematoma has already developed by the time the patient is treated, the hematoma should be evacuated, either by aspiration under aseptic conditions or by actual incision and evacuation of the clots and fluid blood. It goes without saying that such treatment should be carried out in an operating room where bleeding points may be searched for and ligated. Usually it is

not wise to allow a large hematoma to absorb spontaneously. One can never foretell whether tension will progress to such a point that necrosis will occur and although many hematomas will absorb, there are nevertheless two embarrassing things which can occur if this course is followed. As absorption of the hematoma occurs, fibrosis follows and, if the hematoma is about muscles or tendons, this fibrosis may bind moving structures together so that permanent disability occurs. On a number of occasions we have seen a permanent cyst-like cavity remain after the spontaneous absorption of a hematoma, and this cavity permanently fills with serous fluid. Once such a cyst has formed it can be obliterated only by surgical destruction of its lining. In brief, the entire problem in the treatment of a contusion is to prevent subcutaneous bleeding, or if the bleeding has occurred, to evacuate the pool of clotted and fluid blood. Such treatment will prevent necrosis of tissue which occurs from tension and will prevent any disability that may follow the fibrosis of absorption.

Burns.—A discussion of the treatment of burns is not within the compass of this report, but we should like to point out that a burn is a surgical wound that in many respects is no different from other soft tissue injuries. The local treatment of the burned area should be based on the same principles as the treatment of other soft tissue wounds—namely, thorough cleansing, the removal of devitalized tissue, immobilization, and infrequent change of dressing. The Allen-Koch treatment of burns, which is based upon these principles is ideally efficient in the treatment of second-degree burns. As yet there is, in our opinion, no ideal treatment of extensive third-degree burns. In an attempt to solve this problem and to make the treatment of third-degree burns more nearly conform to the fundamental principles of wound treatment, we have completely excised them at once and skin-grafted these areas of excision. This method of treatment is very satisfactory in third-degree burns of 20 to 30 per cent of the body surface, but, unfortunately, it cannot be used with complete safety in very extensive ones. But it is, we believe, a step in the right direction toward the conception of the treatment of all burns as surgical wounds.

Lacerations.—A laceration is a simple incised and contaminated wound in which there is no tissue that is devitalized or damaged. In general, lacerations are wounds made by sharp, clean instruments through a skin which is not dirty and with relatively little injury to the surrounding tissues. Such wounds, after thorough cleansing and irrigation, if seen within six hours after the accident, can be safely closed without débridement. In this connection it is well known that such simple incised wounds about the face and head may be safely treated by primary closure after a much longer period of time has elapsed than is the case when such wounds occur in other parts of the body. If a simple laceration without devitalization of tissue is seen twelve hours or longer after injury, it can be treated by delayed primary closure. Up to the point of closure these wounds are treated in exactly the same manner as those seen within six hours; that is, the wound is thoroughly washed with soap and water, foreign bodies are searched for, and the wound is copiously irrigated with normal salt solution. Following this, the wound may be either frosted with one of the sulfonamides and loosely closed, or it may be packed open with moist saline gauze and protected with a dressing for twenty-four or forty-eight hours. If, on the removal of the pack, the wound appears healthy and uninflamed, it is closed as though no delay had occurred.

Extensive Soft Tissue Injuries.—It is in this type of wound that most trouble is encountered, both from systemic and local infections and also in healing with disability and loss of function. The wound is often caused by both sharp and blunt forces, and as a result there may be loss of tissue, devitalization of the wound edges by contusion, and heavy contamination. After thorough cleansing and removal of foreign bodies, débridement in the true sense—that is, "wound excision"—is carried out. If at all possible the wound is lifted out in mass. In these wounds severance of vital structures makes ideal débridement difficult, but all surfaces of the wound except for severed nerves and tendons and fractured bones can be removed. If fractured bones extend into the wound, torn off or loosened periosteum must be sacrificed. Soiled cortical bone can be removed with a chisel, starting at the clean end of the bone and working toward the fracture site. Severed nerves and tendons are sutured with silk. It is rare that these extensive wounds can be closed without violating the principle of closure without tension. If cortical bone or tendons are not exposed, even very extensive wounds can be "closed" by the application of split-thickness skin grafts so placed as to cover the raw surface entirely. This type of closure does not violate sound surgical principles, for if infection does occur, the grafts will not take and drainage is possible. If the condition of the patient does not warrant the added time necessary to skin-graft the wound or if facilities are not available for carrying out this procedure, then the wound may be frosted with sulfanilamide and left open, or it may be packed with vaseline gauze. In the event that any one of these methods is used, a

snug compression dressing should be applied and a plaster encasement made to insure complete immobilization. This dressing is not disturbed for weeks unless there is an unexplained rise in temperature or abnormal pain. It is our considered opinion that if the circumstances are propitious and the surgeon experienced, many of these wounds which are left open to heal by second intention can be safely closed by the immediate application of skin grafts.

Partial and Complete Avulsions.—An avulsion differs from the wounds just discussed in that even though there is wide loss of tissue, there is often little damage to deeper structures and little devitalization of the wound surface and edges. Avulsions occur most commonly when the clothing of a worker is caught in the gears of a machine and the skin and subcutaneous tissues down to the deep fascia are peeled off the muscle. In some instances the tissues are lost at the scene of accident; in others, they may still be hanging by narrow pedicles. If the tissues are lost, these wounds can be safely grafted after thorough cleansing. Much time is saved for the patient and prolonged disability is often prevented by immediate grafting rather than waiting for the area to granulate and form a scar base which will contract. The type of graft used is the split-thickness graft, which can be cut by hand or with the dermatome. These grafts should be applied so that they entirely cover the wound. The objective is to secure prompt, complete epithelialization of the wound and in this way prevent or minimize scar tissue contracture. In this connection we should note that only grafts of skin from the patient take permanently. Grafts from other persons, even if the blood groups are matched, do not persist. They may in many instances take beautifully at first, but they are always lost in three to five weeks.

The more common type of avulsions is one in which the tissues are widely torn away but still left attached by a pedicle. In these cases, if the flap of torn skin and subcutaneous tissue is merely sutured back in place, there is very often death of at least the distal half of the flap. Presumably this occurs because of thrombosis of veins. Arterial blood is continually pumped into the area, but it cannot escape. Venous engorgement of the flap occurs, the tissues turn purple, and if incised, dark blood escapes. From this point gangrene gradually ensues, and the patient is left with an infected necrotic wound. The possibility of this sequence of events can often be anticipated if the distal portion of the avulsed flap at the time of injury is cyanotic and cold. In such instances it is better to detach the avulsed tissue completely, débride the wound, excise the subcutaneous tissues from the avulsed flap, and reapply the skin as a free full-thickness skin graft. If a compression dressing is applied over this and the part is adequately immobilized, a high percentage of successful growth can be obtained. Furthermore, there is a smaller loss of tissue than there is if the flap is left attached and sutured back in place. This is, of course, an operating-room procedure under strict asepsis. Any infection will cause failure of a full-thickness skin graft to take.

Amputation of Parts.—Occasionally one is presented with the problem of what to do when the tip of a finger, a portion of an ear, the tip of a nose, or some other part is amputated traumatically. If the part is available, is not more than one-half inch long, and has a broad base, there is some prospect of success in immediately suturing it in place and absolutely immobilizing it. We have successfully sutured back in place the tip of a finger amputated through the base of the nail and have seen it completely survive. Success has been reported by others in reattaching a completely amputated tip of the nose. It will be noticed that in both these locations the base of raw tissue through which the amputated part can secure nourishment is broad. It is useless to suture back in place an amputated portion of an ear since the attachment is so narrow that little blood supply can get into the amputated part. However, the cartilage of the severed portion of the ear should always be saved. This can be done by removing the skin and soft tissues from the cartilage and then imbedding the cartilage under the skin of the patient, preferably in a location close to the ear. At a later date this preserved cartilaginous framework can be used in the reconstruction of the missing part. The preservation of a resutured amputated part is a race between autolysis of tissue in the amputated portion and the speed with which blood vessels can grow into it from the attachment at its base. For this reason it is useless to suture back in place large amputated parts.

Wounds with Bones or Tendons Exposed.—Bones and tendons act in much the same manner if they are left exposed in a wound. Cortical bone and tendon that is not covered by tendon sheath, dry and become necrotic if they are exposed to air. Ordinarily the problem of exposed bone is not so difficult as the problem of exposed tendon. A portion of the bone is usually still in contact with soft tissue and will live. Following ultimate healing of the wound, the continuity of the bone will be re-established. However, if tendons are lost, permanent disability occurs. For this reason it is wise to attempt to cover exposed tendon with skin if one can do so without violating surgical principles. Unfortunately, free skin grafts do not take over tendons. If

there is sheath still present over the tendon, then in a fair percentage of instances, free grafts will take, but if the tendonous fibers are exposed the blood supply is not great enough to nourish free grafts. In such cases it is wise to cover the exposed tendon immediately, either by shifting the flaps from the edges of the wound or by the actual transplantation of a flap from some other location. This, of course, means immobilization of the part until the flap has securely grown into place and the pedicle can be severed, which is usually a matter of at least three weeks.

Puncture Wounds.—In civil life there are often wounds made by sharp clean instruments, such as a stab wound with an ice pick, a pistol bullet, or the small puncture made by the sharp end of a bone compounded from within, which, because of the clean conditions under which the wound occurs, can be treated only by local cleansing of the puncture wound. These wounds can usually be cleansed, irrigated, and closed. Bullet wounds more often have to be excised and left open. It is, of course, well known that the conditions under which the wounds occur determine the type of treatment necessary. In general, perfectly clean puncture wounds made with sharp instruments under clean conditions need not be excised and left open. In all other puncture wounds and in any in which there is the possibility of foreign material in the depths of the wound, the tract should be excised, thoroughly cleansed, and then left open or packed with vaseline gauze or gauze on which sulfanilamide has been sprinkled. The great danger in puncture wounds is that anaerobic organisms may be sealed off in the depths of a wound under ideal conditions for proliferation.

Summary

In conclusion we must say that the principles of (1) cleansing, (2) débridement, (3) absolute hemostasis, (4) closure without tension or dead space and with the use of fine interrupted suture material, (5) immobilization, and (6) infrequent change of dressings are not new in the treatment of wounds. They have been advocated in part by every thinking surgeon since the time of Paré. They are, however, time-tested and fundamental, and it requires repetition to help us maintain a proper perspective and a judicial attitude toward new forms of wound therapy that are constantly urged upon us for consideration and adoption.

THE COUNTY SOCIETY

The responsibilities of the county medical society are always great but become even greater in a time of emergency. The county societies never have needed to be more alert to and in touch with the medical needs of the county than at the present time. The society should set the standards for medical service and be the source of scientific information and advice not only to its members but to the public in the county. The county society holds an important place in medicine and in the nation at all times but it is emphasized in any time of emergency as in wartime.

More than ever before the county society should include in its membership all reputable physicians within its province and it should be strongly organized.

The importance of the county society and the continuation of meetings of county societies during wartime was stressed by Col. Fred W. Rankin, president of the American Medical Association, in an address before the Annual Conference of Secretaries and Editors of State Medical Associations in Chicago. Many national organizations of physicians and also some state associations have canceled their annual sessions during 1943, necessitated by the difficulties of transportation and the considerable demand on the time of the physician. Colonel Rankin pointed out that such reasons do not prevail in regard to meetings of county medical societies.

Colonel Rankin stated that the county medical societies are the organizations most concerned with the planning and support of the work of many agencies concerned in the war effort and that requests of the Red Cross, the county and state health departments, the welfare agencies, the groups charged with the organized treatment of venereal disease, the care of the crippled and the tuberculous and of other agencies which undertake important responsibilities during the emergency go to the county medical society.

Furthermore, the county medical society also has the responsibility for recommendations to the Procurement and Assignment Service, the organization of civilian defense, the blood donor program, and, sometimes, for recommendations on the rationing of tires, gasoline, fuel, and food.

Moreover, physicians require during this time, perhaps more than at any other, the mental stimulation of interchange of medical information. It is more important than ever that at the present time county medical societies be most active and supplement as far as possible the work of national associations.—*Editorial, J. Missouri State M. A.*

THE BIRTH OF MEDICAL EDUCATION IN UPSTATE NEW YORK

T. Wood Clarke, M.D., Utica, New York

WHEN, after Queen Anne's War and the building of Fort Hunter, our pioneer ancestors swarmed up the Mohawk Valley, and again when, after the Revolution, they invaded the Oneida country and from there spread north and west to build up new cities in the wilderness of northern, central, and western New York, they were in many ways entirely self-sufficient. They built their own cabins, developed their own farms, shot their own game, and caught their own fish. As long as they retained their health, they could take care of themselves with rifle, plow, and axe. Life was hard, but it was possible. When illness overtook them, however, they were in a sad predicament. Doctors were few and far between.

As the settlements grew, though, medical men followed the pioneers. While a few of these were men of fine education, graduates of the great European universities, many had little or no training. An ambitious young pioneer would come to the wild western country—for everything beyond Albany was considered "the West"—and open a trading post. To the usual stock of hardware, clothing, boots, hats, sugar, and tobacco he would add a few simple drugs. These he would sell to his suffering neighbors. Soon he would begin calling on them in their homes to administer the drugs, and, in a remarkably short time, would add the prefix "doctor" to his name and become the owner of a more or less flourishing practice. Some had a few months' apprenticeship in another physician's office. Still others were frank quacks, extolling wonderful cure-alls supposed to be secret formulae acquired from the Indian. Of laws there were none; of rules of practice there were none; and of means of protecting the unfortunate patient there were none.

In 1800 there were but five medical schools in North America. In 1765 a school had been opened in Philadelphia, later to become part of the University of Pennsylvania, and in 1768 King's College, in New York, whose name after the Revolution was changed to Columbia, had added a medical department. These had been followed by Harvard in 1783, Dartmouth in 1798, and Transylvania, in Lexington, Kentucky, in 1799.

In 1792 a young man of 20, Westel Willoughby, recently licensed by the Connecticut State Medical Society, came up the Mohawk Valley and turned his face northward to the Royal Grants, the territory between the East and West Canada Creeks, now Herkimer County, which at this time was rapidly becoming populated by settlers of both German and English ancestry. He settled first in Norway, but later moved to Newport on the West Canada Creek. He soon made his presence felt in the young community, was elected Judge of the Court of Common Pleas in 1805, went to the State Assembly in 1807, and to Congress in 1814.

A few years after Dr. Willoughby settled in Norway the Rev. Caleb Alexander, a Presbyterian missionary, a graduate of Yale College, came to the village of Fairfield. At that time Fairfield, a flourishing and rapidly growing settlement situated at an important crossroads high in the hills north of Little Falls, was the business and political center of the Royal Grant lands.

Many of the post-Revolutionary settlers of this territory were New Englanders of culture and education. As their families increased they felt the need of a school in which their children could be educated and appealed to Mr. Alexander and to Dr. Willoughby to organize one. The result was that in 1803 the Fairfield Academy opened its doors and began a career which for over a hundred years was to have a marked influence on the education and culture of New York State. Mr. Alexander became its first president.

By 1809 the Academy had attained such success that it added to its equipment a stone building to be used as a laboratory. In this Dr. Josiah Noyes, a graduate of Dartmouth, delivered lectures on chemistry and Dr. Jacobs, of Canandaigua, on anatomy. These lectures were attended not only by the students of the academy but also by neighboring physicians as well. They were so popular that the board of trustees, of whom Dr. Willoughby was an influential member, determined to form a regular medical school. With this thought in mind Dr. Noyes wrote to Dr. Lyman Spalding in Portsmouth, New Hampshire, under whom he had studied at Dartmouth.

Lyman Spalding was born in Cornish, New Hampshire, June 25, 1775. Dr. Nathan Smith, of that village, took an interest in the boy and directed his education. Young Spalding studied

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 5, 1943.

medicine with Dr. Smith and later, after graduating from the Harvard Medical School, returned to his preceptor and assisted him in founding the medical department of Dartmouth in 1797. For some years Drs. Smith and Spalding comprised the entire faculty of the school, Dr. Spalding teaching anatomy and chemistry and Dr. Smith all other branches of medicine.

In 1799 Dr. Spalding resigned from Dartmouth, and moved to Portsmouth, New Hampshire, where he soon became an outstanding figure in the community. When Waterhouse obtained his first samples of Dr. Jenner's newly discovered cow-pox vaccine for smallpox, Dr. Spalding became his representative in Portsmouth, and for a number of years held a monopoly on vaccination in that part of New Hampshire, paying Dr. Waterhouse 25 per cent royalty on all funds received for vaccinating.

In his letter to Dr. Spalding, Dr. Noyes described the Fairfield Academy in these words: "It is expected that the Academy and Medical Institution connected will take the name of 'College' soon. The instruction at present is about the same as is given in the most respectable colleges in the United States. The number of students besides Medical Students is generally from 90 to 115. The Rev. Caleb Alexander is the Principal. There is, besides, one Tutor and an assistant who attends to the lower branches. We have three buildings, one of stone called the Laboratory, containing 14 elegant rooms. There are two lecturing rooms, one for Anatomy, and the other for lectures on Chemistry. These two rooms perhaps are better than any others built for the same purpose in the United States, except Philadelphia. Our Chemical Apparatus is more complete than any in the City of New York, and the Anatomical Museum is equal to Dr. Smith's at Dartmouth." He then went on to offer Dr. Spalding the chair of anatomy and invited him to visit the school.

Dr. Spalding accepted the invitation and in October, 1810, set out for Fairfield. On his way he stopped over in Boston and persuaded his friend, Dr. George Cheyne Shattuck, to go to Fairfield to lecture on the theory and practice of medicine. Each gave a six weeks' course of lectures which were so successful that Dr. Spalding was offered the chair of anatomy and surgery and Dr. Shattuck that of the theory and practice of physic and physiology. Shortly after this Dr. Willoughby was made professor of obstetrics. These, with Dr. Noyes, who retained the chair of chemistry, made up the medical faculty of the Fairfield Academy. The session held in the autumn of 1811 by these four professors was eminently successful.

Even before this session was held the ship of Fairfield was sailing through dangerous waters. Dr. Jacobs, who had been superseded by Dr. Spalding as professor of anatomy, had returned to Canandaigua and was endeavoring to found a medical school there. Rev. Eliphalet Nott, the president of Union College, was making every effort to persuade Fairfield students to go to Union, even going so far as to have grappling hooks thrown onto the boats of students headed up the Mohawk for Fairfield, and mooring them to the docks at Schenectady. The most serious opposition, however, came from Utica and Clinton.

The trustees of Oneida Academy at Clinton were making strenuous efforts to receive a charter as a college and to have a medical department in Utica. General Jonas Platt, one of the backers of the Oneida Academy project, a political power in the State, induced the legislature to withhold the appropriation of $5,000 which it had previously given to Fairfield, and to favor the project of the Oneida Academy, with the result that early in 1812 a collegiate charter was issued to the Clinton school under the name of Hamilton College. The Hamilton trustees immediately appointed the entire medical staff of the Fairfield Academy—Drs. Noyes, Shattuck, Spalding, and Willoughby—to professorships at Hamilton, and intimated to Mr. Alexander that the position of president was awaiting him.

Promptly, without giving the trustees even a day's notice, President Alexander, Professor Noyes, and a tutor, Mr. Montague, resigned their positions at Fairfield and accepted appointments at Hamilton. Mr. Alexander wrote to Drs. Spalding and Shattuck explaining the situation and urging them to follow their example. Dr. Willoughby seems to have accepted the appointment at Hamilton without resigning from Fairfield. Upon receipt of Mr. Alexander's letter, Dr. Spalding wrote to Dr. Shattuck, urging him to stick to Fairfield, and to the deserters, refusing to join them in the change. To Judge Smith, one of the trustees of Fairfield, he wrote that "So long as Fairfield stands by me I will stand by Fairfield." Dr. Shattuck, however, had decided that lecturing in central New York interfered with his practice in Boston, resigned from Fairfield, and refused to accept the appointment from Hamilton.

The firm stand taken by Dr. Spalding undoubtedly saved the school at Fairfield. One of the most important factors which induced the legislature to charter Hamilton College was the information given to them that both Dr. Spalding and Dr. Shattuck would accept professorships there. When they refused, the whole picture changed. Hamilton abandoned the plan of having a medical department, and the legislature

issued a charter to the Fairfield Academy for a medical school to be called the College of Physicians and Surgeons of the Western District of New York. Dr. Willoughby returned to the fold as professor of obstetrics. Dr. James Hadley, a graduate of Dartmouth, the grandfather of President Arthur Twining Hadley, of Yale, was made professor of chemistry in the place of the deserting Dr. Noyes, and Dr. Spalding taught everything else—anatomy, medicine, and surgery. In April, 1813, Dr. Spalding was elected to the presidency. While he retained the chair of anatomy and surgery, Dr. John Stearns was appointed to the chair of the theory and practice of physic. Dr. Stearns, after graduating from Yale and doing postgraduate work in Philadelphia, had settled in Albany and then in Saratoga County. He founded the Medical Society of the State of New York, served for many years as its secretary, and four times was elected to the office of President. Later he moved to New York City, where he organized and served as the first president of the New York Academy of Medicine.

The success of any school depends upon the quality of its teachers. With these four men on the faculty and no rival medical school nearer than New York City and Boston, the College of Physicians and Surgeons of the Western District of New York grew with astonishing rapidity, so that, when it reached its zenith, in 1833, with an enrollment of 217 students, it was, except for the school in Philadelphia, the largest medical college in the United States. Its students came from as far east as Maine and as far west as Illinois. New Jersey, Pennsylvania, Michigan, Vermont, New Hampshire, Connecticut, and Ohio all sent their quotas. As time went on, more and more came from north of the border in what was then known as Upper Canada.

Compared with the present-day requirements for admission to medical schools, those of Fairfield were simple. The student, if he had no college education, must have an acquaintance with Latin (the intimacy of the acquaintanceship is not specified), and he must have a correct knowledge of English grammar and natural and experimental philosophy. He must also sustain a fair moral character. How fair this must be was also omitted from the bylaws. To be candidate for the degree of Doctor of Medicine he must have studied for three years under a reputable physician and attended the college for two terms of twelve weeks each. The length of the terms was later increased to sixteen weeks. If he fulfilled these requirements, he was examined by the members of the faculty in anatomy, surgery, obstetrics, chemistry, materia medica, minerology, and the institute of medicine. He must also present and defend a thesis. If the student succeeded in these, the faculty of the school recommended him to the Regents of the State of New York, who conferred upon him the degree of Doctor of Medicine, which carried with it the license to practice.

The members of the faculty, except for Dr. Hadley, and, later on, Dr. Delamater, did not live at Fairfield. While Dr. Willoughby resided in the neighboring town of Newport, Dr. Spalding, during his first years in the school, lived in Portsmouth, New Hampshire, and later, even when acting as president of the college, resided in New York City, while Dr. Stearns kept his home in Saratoga County. The college terms lasted through the months of October, November, and December. Dr. Hadley delivered one lecture each day during the three months. The other professors would come to the school at an appointed time, deliver two and sometimes three lectures a day for one month, and then either return to their homes to practice or, in later years, when medical schools became more numerous, go on to some other school for another course. In some cases these peripatetic teachers delivered lectures in as many as four or five colleges in a single winter.

The students enrolled for as many courses as they wished, paying from ten to twelve dollars to each professor for his course. After attending a course for two terms students were privileged to sit in on all future lectures without charge.

This system had two advantages: first, a student, who in many cases was already a practicing physician, might absent himself from his practice for only a few weeks at a time, taking one or two courses a year, and at the end of several years have attended enough to earn the coveted M.D. without seriously interfering with his practice, and, second, it stimulated the professors to their best efforts. The more interesting and useful the teacher made his lectures, the more students enrolled under him and the larger was his income.

While this entire setup, in the light of modern medical education, seems primitive in the extreme, it was a conscientious effort to raise the standards of medical practice of the time. This is well shown by the character and careers of the graduates of the school, among whom were numbered some of the leading medical men of the country. These included such influential persons as Dr. Charles Coventry, of Utica, president of the Medical Society of the State of New York, through whose influence the first state hospital for the insane in New York State was founded, and Dr. Asa Gray who, after graduating from Fairfield and teaching botany in the school, went

medicine with Dr. Smith and later, after graduating from the Harvard Medical School, returned to his preceptor and assisted him in founding the medical department of Dartmouth in 1797. For some years Drs. Smith and Spalding comprised the entire faculty of the school, Dr. Spalding teaching anatomy and chemistry and Dr. Smith all other branches of medicine.

In 1799 Dr. Spalding resigned from Dartmouth, and moved to Portsmouth, New Hampshire, where he soon became an outstanding figure in the community. When Waterhouse obtained his first samples of Dr. Jenner's newly discovered cow-pox vaccine for smallpox, Dr. Spalding became his representative in Portsmouth, and for a number of years held a monopoly on vaccination in that part of New Hampshire, paying Dr. Waterhouse 25 per cent royalty on all funds received for vaccinating.

In his letter to Dr. Spalding, Dr. Noyes described the Fairfield Academy in these words: "It is expected that the Academy and Medical Institution connected will take the name of 'College' soon. The instruction at present is about the same as is given in the most respectable colleges in the United States. The number of students besides Medical Students is generally from 90 to 115. The Rev. Caleb Alexander is the Principal. There is, besides, one Tutor and an assistant who attends to the lower branches. We have three buildings, one of stone called the Laboratory, containing 14 elegant rooms. There are two lecturing rooms, one for Anatomy, and the other for lectures on Chemistry. These two rooms perhaps are better than any others built for the same purpose in the United States, except Philadelphia. Our Chemical Apparatus is more complete than any in the City of New York, and the Anatomical Museum is equal to Dr. Smith's at Dartmouth." He then went on to offer Dr. Spalding the chair of anatomy and invited him to visit the school.

Dr. Spalding accepted the invitation and in October, 1810, set out for Fairfield. On his way he stopped over in Boston and persuaded his friend, Dr. George Cheyne Shattuck, to go to Fairfield to lecture on the theory and practice of medicine. Each gave a six weeks' course of lectures which were so successful that Dr. Spalding was offered the chair of anatomy and surgery and Dr. Shattuck that of the theory and practice of physic and physiology. Shortly after this Dr. Willoughby was made professor of obstetrics. These, with Dr. Noyes, who retained the chair of chemistry, made up the medical faculty of the Fairfield Academy. The session held in the autumn of 1811 by these four professors was eminently successful.

Even before this session was held the ship of Fairfield was sailing through dangerous waters. Dr. Jacobs, who had been superseded by Dr. Spalding as professor of anatomy, had returned to Canandaigua and was endeavoring to found a medical school there. Rev. Eliphalet Nott, the president of Union College, was making every effort to persuade Fairfield students to go to Union, even going so far as to have grappling hooks thrown onto the boats of students headed up the Mohawk for Fairfield, and mooring them to the docks at Schenectady. The most serious opposition, however, came from Utica and Clinton.

The trustees of Oneida Academy at Clinton were making strenuous efforts to receive a charter as a college and to have a medical department in Utica. General Jonas Platt, one of the backers of the Oneida Academy project, a political power in the State, induced the legislature to withhold the appropriation of $5,000 which it had previously given to Fairfield, and to favor the project of the Oneida Academy, with the result that early in 1812 a collegiate charter was issued to the Clinton school under the name of Hamilton College. The Hamilton trustees immediately appointed the entire medical staff of the Fairfield Academy—Drs. Noyes, Shattuck, Spalding, and Willoughby—to professorships at Hamilton, and intimated to Mr. Alexander that the position of president was awaiting him.

Promptly, without giving the trustees even a day's notice, President Alexander, Professor Noyes, and a tutor, Mr. Montague, resigned their positions at Fairfield and accepted appointments at Hamilton. Mr. Alexander wrote to Drs. Spalding and Shattuck explaining the situation and urging them to follow their example. Dr. Willoughby seems to have accepted the appointment at Hamilton without resigning from Fairfield. Upon receipt of Mr. Alexander's letter, Dr. Spalding wrote to Dr. Shattuck, urging him to stick to Fairfield, and to the deserters, refusing to join them in the change. To Judge Smith, one of the trustees of Fairfield, he wrote that "So long as Fairfield stands by me I will stand by Fairfield." Dr. Shattuck, however, had decided that lecturing in central New York interfered with his practice in Boston, resigned from Fairfield, and refused to accept the appointment from Hamilton.

The firm stand taken by Dr. Spalding undoubtedly saved the school at Fairfield. One of the most important factors which induced the legislature to charter Hamilton College was the information given to them that both Dr. Spalding and Dr. Shattuck would accept professorships there. When they refused, the whole picture changed. Hamilton abandoned the plan of having a medical department, and the legislature

wooden chapel standing lonely and forelorn, four miles east and seven hundred feet above the little village of Middleville in the valley of the West Canada Creek. It is now used as a Grange Hall.

Discussion

Dr. Howard Dittrick, *Cleveland, Ohio* (by invitation)—There are many features of Dr. Clarke's paper which I should like to discuss, but I shall limit my remarks to the influence that the Fairfield school exercised over medical education in Ohio. The more one learns of these early medical schools, the more one respects the conscientious and efficient teaching that was done in such schools as Fairfield. Furthermore, the courage with which the graduates carried on amid pioneer conditions fills us with wonder and admiration. One of Fairfield's students who was unable to attend more than one term subsequently became a professor of surgery. A record of one of his morning operative clinics reveals that in addition to excision of a jaw and other general surgical procedures, he performed five eye operations.

The Fairfield influence in Ohio extended as far south as Cincinnati. Dr. D. A. Tucker writes me that Dr. Reuben D. Mussey, who was a professor in the Medical College of Ohio and who was the leading surgeon in the Middle West, taught at Fairfield one or two years before coming to Cincinnati. This would have been about 1836 or 1837.

However, it is the Western Reserve school which is especially indebted to this New York State School. In the early part of the nineteenth century there was a considerable settlement of Western Reserve by former residents of central New York State. In the little village of Chagrin on the south shore of Lake Erie near the mouth of the Chagrin River, a group of public-spirited citizens had a vision like that of the founders of Fairfield. Furthermore, there existed such a strong attachment to Fairfield that in 1834 they founded an institution which they named the Willoughby University of Lake Erie. Six weeks after medical teaching began they went even further and changed the name of the village to Willoughby. It was thought the new name would attract students because of the prestige of Dr. Westel Willoughby, the president of Fairfield Medical College, among the many graduates of that school in the Middle West. It may also have been true that, like present-day educators, the founders hoped for the sustaining financial interest of this wealthy physician.

The Willoughby school was patterned after the Fairfield Medical School, and several teachers and former students of Fairfield were members of the Willoughby faculty. Dr. Amasa Trowbridge, professor of surgery, and Dr. John Delamater taught in both schools simultaneously. Francis W. Walsh, another professor of surgery; Orson S. St. John, professor of materia medica, pharmacy, and medical jurisprudence; John Lang Cassells, the dean, were all graduates of Fairfield. Dr. George W. Card and Dr. John M. Henderson, successful practitioners of Willoughby and also two of the founders of the local school, had both studied at Fairfield. Dr. Horace A. Ackley, who taught surgery, Dr. T. W. Donavan, and Dr. George Jones had attended some sessions at Fairfield. In 1847, because of the rivalry of a recently founded school in nearby Cleveland, the Willoughby school was forced to move its equipment to Columbus. After three months its charter was canceled, and it was replaced by the Starling Medical School in that city. Later this school fused with another and became the College of Medicine of Ohio State University, which is still active.

As I have intimated, the troubles at Willoughby began with the founding in 1843 of the Medical Department of Western Reserve College. This year in Cleveland we are celebrating the centenary of this school, which is now known as the Medical Department of Western Reserve University. During the years 1843 and 1847 there was bitter rivalry between the two schools, which were only twenty miles apart. Such measures as processions, vitriolic newspaper articles, and even stealing students were probably similar to the methods taken by other schools to undercut Fairfield. Curiously enough, the action of the faculty members at Willoughby was also similar to Fairfield's experience with Hamilton College. Dr. John Delamater, Dr. Horace A. Ackley, and Dr. John Lang Cassells joined forces with the Cleveland group.

I have given the names of the professors of the Willoughby school who had been connected with Fairfield. In Cleveland, medical education had a similar origin. During its first year the faculty of the Medical Department of Western Reserve College had four teachers who had been associated with Fairfield. Dr. John Delamater taught in both schools. Dr. John Lang Cassells had graduated from Fairfield, while Dr. Horace A. Ackley and Dr. Jacob Delamater had been students there but had not graduated.

Dr. F. C. Waite, to whom I am indebted for this historical data, is publishing a book to appear later this year, entitled "The History of the First 100 Years of the Medical Department of Western Reserve University." It will contain a chapter showing the inter-relation of these early medical schools.

Among the material associated with medicine in these pioneer days, now deposited in the Museum of the Cleveland Medical Library, we have all the manuscripts belonging to a student who graduated from Western Reserve in 1846. Complete notes of lectures given by the professors throw much light on the teaching of that era. For example, one of the faculty had studied in Paris, and in teaching physical diagnosis he described the signs revealed by percussion and auscultation, the first time the new methods had been taught in the west. This was only about twenty years after Laennec's discovery, and France was a long way from the Western Reserve one hundred years ago.

Horace Ackley, the Fairfield student who became professor of surgery in the Cleveland school, was a dynamic force in this group. He was the first surgeon in Ohio to use ether as a general anesthetic.

to Michigan and then to Harvard and became world renowned as America's greatest botanist.

In 1815 Dr. T. Romeyn Beck succeeded Dr. Stearns as professor of the practice of medicine at Fairfield. In the year 1817, Dr. Spalding, then a resident of New York City, who was enjoying a rapidly increasing practice and was a trustee of the College of Physicians and Surgeons of Columbia University, resigned his presidency and professorship at Fairfield and was succeeded by Dr. Joseph White, of Cherry Valley, New York. Dr. Spalding remained in New York and attained national fame as the proposer and author of the first edition of the *United States Pharmacopœia*, the work which brought order out of chaos in the science of materia medica in America.

Dr. White, who was considered the greatest surgeon in the western district, soon split up the work done by Dr. Spalding and appointed his son, Dr. Delos White, professor of anatomy and physiology but served as professor of surgery until 1827, when he resigned that post and was succeeded by Dr. John Delamater. However, he retained the presidency of the college for five years more and was then followed by Dr. Willoughby, who held the presidency until the school closed.

In 1822 Dr. Delos White resigned the chair of anatomy and physiology because he could not get enough bodies to dissect, and was succeeded by Dr. James McNaughton. In 1839 Dr. Delamater was transferred from the chair of surgery to that of medicine and obstetrics, and Dr. Frank H. Hamilton was made professor of surgery.

Following its peak year in 1833 the prosperity of the Fairfield school declined rapidly. Many important influences were working against it. In 1835 the Geneva College, which later changed its name to Hobart, opened a medical department. To the east Albany was making strides medically. Dr. Alden Marsh, professor of anatomy and physiology in the Vermont Academy of Medicine at Castleton, Vermont, had been conducting private classes in anatomy and surgery in Albany since 1820. In 1831 he was joined by Dr. James H. Armsby. In 1839 these two, with the cooperation of other Albanians, obtained a charter for the Albany Medical College. In its early days before the Erie Canal was opened and railroads were built, Fairfield, though perched on the top of the hills above Little Falls, was as accessible as any other spot in upstate New York. With the coming of more rapid methods of transportation and with the railroads going directly to Geneva and to Albany, Fairfield was hopelessly handicapped. When the enrollment, which had increased from 18 in 1813 to 217 in 1833, dropped in six years to 101, it became evident that the competition of the new schools was too much for it. At the end of the fall and winter term of 1839–1840 the trustees voted to abandon the medical department and turn its buildings back to the Fairfield Academy. Drs. Delamater, Hadley, and Hamilton accepted appointments at the New Geneva school while Drs. Beck and McNaughton, who lived in Albany, became members of the school in that city. Dr. Beck attained immortality as the author of the first textbook on medical jurisprudence, the foundation stone which has served as a basis for all later works on the subject.

The College of Physicians and Surgeons of the Western District of New York, which, a few years before ranked so high among American medical schools and had done so much to raise the standards of medical practice throughout the Northern States and Canada, was a thing of the past.

The acquisition of the three famous teachers from Fairfield gave the Geneva school a great boom. In three years its enrollment had increased from 76 to 195. It was, however, doomed to the same fate that Fairfield suffered. In 1843 Dr. Delamater, with the assistance of two of his former students at Fairfield, Drs. Ackley and Cassells, founded the Cleveland Medical College, which later became the Medical Department of Western Reserve University and is this year celebrating its one hundredth anniversary. In 1846 three of its outstanding teachers, Dr. Hamilton, Dr. Charles Coventry, of Utica, and Dr. Austin Flint, Jr., organized the Buffalo Medical College. These diverted the students from the west and from Canada to the new schools, and the attendance at Geneva fell in twelve years to 12 students. From then on it had a precarious existence, and in 1872, two years after the University of Syracuse was opened, the school, its library, and its laboratories were moved to that city and became the Medical Department of the University of Syracuse. Later the Buffalo Medical College was incorporated into the University of Buffalo, and the Albany Medical College became part of Union College. All of these, however, as well as many of the medical schools of the Middle West, were the children and grandchildren of the College of Physicians and Surgeons of the Western District of New York at Fairfield.

After the medical school at Fairfield had closed its doors, the Academy continued its successful career, at one time as a coeducational institution of learning and later as a military school. Early in the present century this, too, was forced to disband. For years the old stone buildings remained empty and were finally torn down. The stone was used to build a state road. Today all that remains of this famous school is the old

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

Fourth Medical Division of Bellevue Hospital

Date: July 1, 1943
Presented by: Dr. Max Trubek

Dr. Mary Finck: This was the first Bellevue admission of a 45-year-old white man who was in good health until three days prior to admission, when he developed chills and fever appearing several times daily. Two days later he developed left chest pain which was constant and did not radiate from the anterior chest. The pain was pleuritic in type. A "cigarette cough" that had been present for several months became more severe and was productive of small amounts of white sputum, which had never been blood-streaked. There were no gastrointestinal or genitourinary symptoms. The family history was negative. Past history revealed that the patient had been a morphine addict since 1911. He had taken the drug intravenously until eight months ago and had been taking 1½ grains daily subcutaneously since then. The remainder of the history was noncontributory.

On admission, the patient's temperature was 103 F.; pulse, 88; respirations, 22; and the blood pressure, 92/54. Physical examination revealed a slender, poorly nourished white man in no acute distress but who appeared chronically ill. There was no dyspnea, cyanosis, or orthopnea. The skin was clear. The pupils were round, regular, and equal and reacted to light and accommodation. Examination of the fundi was negative. The ears, nose, and throat were negative except for pharyngeal injection. There was bilateral cervical adenopathy with small, discrete, nontender nodes. The neck was supple, and the trachea was in the midline. The thorax was symmetric, with slight lag on the left. No rub was present. Examination of the left lung disclosed normal resonance throughout with bronchovesicular breath sounds and slightly increased voice sounds at the base. There were no rales. The heart was not enlarged. Regular sinus rhythm was present, and the second aortic sound was greater than the second pulmonic. A loud, rough systolic murmur was heard over the aortic and pulmonic regions. There was a questionable, short, diastolic murmur at the apex. No thrill was noted. The abdomen was soft, and no masses, viscera, or tenderness were palpable. Examination of the extremities revealed numerous scars from intravenous injections. No clubbing, cyanosis, or edema was noted. The reflexes were physiologic.

Laboratory Findings on Admission.—The white blood count was 12,300 with 83 per cent polymorphonuclears, 15 per cent lymphocytes, and 2 per cent monocytes. The hemoglobin was 11.0 Gm., with a red blood count of 5,000,000. A careful search of the blood smear failed to reveal any malarial organisms. The urine was of amber color, with specific gravity of 1.030, acid reaction, and a faint trace of albumin and sugar; microscopic examination was negative. The blood Wassermann was negative and the erythrocyte sedimentation rate was 2 mm. per hour. A roentgenogram of the chest revealed the heart to be enlarged in the transverse diameter, with interstitial changes and fibrosis at the roots of both lungs. An electrocardiogram revealed a PR interval of 0.20 second, a QRS of 0.08 second, and elevation of R-T segment in lead 2. There was sinus rhythm of average rate and activity suggested.

Course.—The patient ran a febrile course, the temperature ranging from normal to 103 F. daily, with occasional spikes to 104 F. Repeated smears for malarial organisms were negative. Repeated urinalyses were negative except for a faint trace of albumin. On May 14, 1943, the eleventh hospital day, blood culture was reported positive for Streptococcus viridans. Subsequent cultures confirmed this finding. On May 18, 1943, the fifteenth hospital day, it was noted that the systolic murmur over the precordium was definitely rougher in quality. A three-day trial of atabrine produced no response. The patient's course was steadily downhill, and on the twenty-first hospital day an increased harshness of the aortic murmur as well as pronounced apical systolic and diastolic murmur were noted. At this time one observer thought the spleen was palpable. The blood pressure remained low. Petechiae never were found, but a café-au-lait discoloration of the skin was observed by one examiner as developing some time after admission. An electrocardiogram taken on the twenty-first hospital day showed active changes with an increase of the PR interval to 0.27 second, a decrease of the T waves in lead 1, an inverted T in lead 4, and a marked incomplete auriculo-ventricular block.

It was decided to use massive doses of chemo-

John Delamater must have been a remarkable man. A peripatetic teacher, he taught in nine medical schools, and his courses involved every subject in the curriculum. He was equally skilled in diagnosis, internal medicine, surgery, and obstetrics, and was regarded as the foremost medical teacher of his day.

In the course of looking over his book of prescriptions written for his Cleveland patients in 1843, we conclude that he was a wise and careful physician, as well as being orderly and systematic in his methods. We obtain a passing glimpse of the ills of Cleveland's first families from his record of the remedies he used.

It is evident, therefore, that medicine in the Western Reserve derived lasting benefit from its roots in Fairfield. Reserve was blessed in being born of good stock, and we are happy to assure you that it has remained worthy of its distinguished heritage.

NEUROPSYCHIATRY IN THE ARMY

Under "Medicine and the War" in a recent issue of the *J.A.M.A.* appears a brief report of the establishment of a special school for neuropsychiatry under the auspices of the United States Army Medical Corps.

Psychiatric problems represent today some of the most important of those that confront our armed forces. In 1918 there were 7 men of each thousand discharged for psychiatric reasons, whereas in 1942 the rate was 4 per thousand. At the time of induction in 1918 only 20 men of each thousand were discharged for psychiatric reasons; now about 75 of each thousand are rejected for such causes. This does not mean that more men are now mentally unfit; our scientific methods have improved sufficiently in the interval to enable more accurate detection of such cases. The indications are that 30 per cent of the casualties now arriving from the war zones are psychiatric in character or have some well-defined psychiatric aspects. . . . .

The need for special consideration of neuropsychiatric problems was recognized early after our entrance into the war with the establishment of a committee for this purpose in the Division of Medical Sciences of the National Research Council.

In February, 1942, a Neuropsychiatry Branch was established in the Surgeon General's Office under Lieut. Col. Patrick S. Madigan, who had many years of experience in this specialty in the Regular Army. . . . .

Among the most important duties of the branch are (1) giving advice to the Surgeon General and other governmental agencies on neuropsychiatric matters, (2) recommending policies for the Army in neuropsychiatric matters, (3) inspecting neuropsychiatric facilities in hospitals and clinics, (4) making recommendations for circular letters and directives regarding neuropsychiatric matters, (5) reviewing neuropsychiatric information coming into this office, (6) maintaining a card index of location and qualifications of neuropsychiatric officers, (7) consulting with the personnel division and recommending assignments and transfers of neuropsychiatric officers, (8) reviewing and approving scientific publications submitted by neuropsychiatric officers, and (9) attending and participating in National Research Council meetings.

As this section of the Surgeon General's Office became oriented in its responsibilities, consultants were appointed to coordinate and supervise clinical and administrative neuropsychiatry.

Most important in this service has been the establishment of the School of Military Neuropsychiatry, which has already trained more than 120 officers. A neuropsychiatric unit at the Thirty-Sixth Station Hospital has been organized under the command of Lieut. Col. Ernest H. Parsons. This unit is functioning as a neuropsychiatric center in the European theater and is providing indoctrination instruction for newly arrived neuropsychiatric officers so that they may familiarize themselves quickly with the problems and case material. Especially qualified trained psychiatrists have been assigned to carry out planned mental hygiene programs at replacement training centers.

The question of morale is being met by liaison established between the Neuropsychiatric Branch and the Special Services Branch of the Army.

Finally, neuropsychiatry in the armed forces must be especially concerned with problems of delinquency. The crude methods of the past have given way to more humane and satisfactory handling of the problems of the homosexual. No longer is it necessary to subject cases that are so definitely in the medical field to the routine of military court martial.

The development of the Neuropsychiatric Branch of the United States Army Medical Department represents one of the most important achievements in the advancement of military medical science. All of those officially responsible merit commendation for their cooperation in the significant results that have already been secured.

THE GENTLE HAND

Parson: "Rastus, that's a fine garden you have there."

Rastus: "Yah suh, Pahson."

Parson: "You must thank the Almighty for it."

Rastus: "Pahson, did you ebbah see dis piece of ground when de Almighty had it all to Hisself?"

congenital defect. Either could be the cause e, for the history in a morphine addict is apt be inaccurate.

Another point I should like to make is the fact it while inoculation subcutanesusly or intrave- usly with Str. viridans is possible, it is not too ely. The organisms more apt to be so injected the Staphylococcus, Str. haemolyticus, or rtain molds. While the lack of emebolic phe- mna is somewhat against the diagnosis of bacute bacterial endocarditis, we must re- ember that these phenomena are accidents which ay or may not take place and that they are most always present when the disease runs a asonably lengthy course, rather than the rela- vely short one that we have in this instance.

DR. HAROLD J. LIVINGSTON: I saw this pa- ent shortly after admission and noted a dias- olic murmur at the apex. I thought the mur- ur to be of rheumatic origin with superimposed ubacute bacterial endocarditis.

DR. MAXWELL L. GELFAND: My impression as also that of an old rheumatic lesion with uperimposed subacute bacterial endocarditis.

Presentation of Pathology

DR. IRVING GRAEF: At autopsy, the skin and mucous membranes were free of petechiae. There was no external edema. The tips of the fingers were slightly enlarged, suggesting slight clubbing. The only significant visceral findings concerned the heart, spleen, and liver. The pericardial sac was obliterated by fine adhesions and a fibrinous exudate that could be readily detached. In some places, there were hemorrhagic extravasations in the epicardium, 2 to 3 mm. in diameter.

The heart was enlarged and weighed 700 Gm. with the aorta attached. The chambers were not disproportionately enlarged. Upon opening the right auricle, a firm vegetation, cylindrical in shape and measuring a centimeter in height and diameter, was found just above the auricular attachment of the septal leaflet of the tricuspid valve. It was dense, yellowish-red, and appeared to be covered with endothelium. The endocardium elsewhere in the right auricle and ventricle, as well as on the tricuspid and pulmonic leaflets, was not remarkable. The left auricle was free of thrombi, and the mitral valve and its leaflets were unchanged, except for a very fine row of glistening vegetations (less than 1 mm. in height and thickness) along the contact margin of the anterior leaflet of the valve. The leaflets were freely movable, otherwise thin and not fused at their commissural junctions. The chordae tendineae were thin, delicate, and discrete, and the papillary muscle not unduly hypertrophied or scarred.

The left ventricle was greatly dilated, and the wall measured 1.6 cm. in thickness near the base.

The aortic valve was remarkable. Only two cusps were discerned; one appeared to be of normal breadth and the other was twice as wide. Their commissural junctions were slightly fused and both leaflets were covered with partly friable, partly dense, reddish-brown vegetation, intimately attached to the underlying cusps. On section, the substance of the cusps could be discerned—fibrosed and partly calcified. The remains of a raphe were evident midway between the commissural attachments of the large cusp but its height could not be determined because of a large mycotic aneurysm which encroached upon it medially and posteriorly. This aneurysm extended through the inter-auricular septum and furnished the base for the polypoid vegetation above the tricuspid valve. Another mycotic aneurysm extended downward from the sinus of Valsalva into the myocardium of the interventricular septum and to the overlying epicardium. Where it involved the myocardium, it contained friable muscle and necrotic exudate. The coronary arteries were patent and not sclerotic. The myocardium on section was firm, beefy red, and exhibited no scarring.

The liver was enlarged, weighing 2,000 Gm. On section it presented a mottled appearance; some areas were lighter than others, and the lobular markings seemed prominent. The spleen was enlarged and weighed 450 Gm. It was firm, and on section it presented a reddish-pink tinge with prominent corpuscles. The red pulp was dense and not friable. No infarcts were seen.

Microscopic examination disclosed no rheumatic stigmata in sections of the left auricle, mitral cusps, and their attachments, interventricular septum or papillary muscles. There were no Aschoff bodies and no perivascular, endocardial, or intrafascicular scars. The section including the epicardium disclosed a diffuse inflammatory reaction, with a slight purulent and fibrinous exudate on the surface. Sections through the aortic leaflets disclosed a calcified fibrous core representing the remains of the cusps covered by compressed layers of fibrin, fragmented leukocytes including polynuclear and mononuclear cells. Bacterial colonies (gram-positive cocci) were profuse on the surface of the vegetation, and in some places in the deeper layers as well. There was little evidence of organization in the sample sections taken, but in places there was a considerable mononuclear cellular response near the vegetation.

Sections of the liver disclosed mild passive congestion with dilatation of the central veins and slight atrophy, together with fatty change of the adjacent liver cells. The portal areas

therapy, but on the morning of the twenty-second hospital day, the patient developed a sudden chill, with a temperature rise to 104.8 F., followed shortly by the development of auricular fibrillation with marked dyspnea, cyanosis, and a short episode of generalized rigidity followed by tremors and facial twitching. Respirations became increasingly rapid and shallow, and the patient died three hours later, twenty-four days after the onset of his illness.

Discussion

DR. MAX TRUBEK: The seeming abrupt onset and accelerated course of this patient's illness places it outside the category of sepsis lenta, in spite of the findings of Str. viridans on repeated blood cultures. Not all drug addicts who come with a febrile state have malaria. We have had at Bellevue several such cases with sepsis and endocarditis where the spiking temperature and splenomegaly at first suggested the more usual diagnosis of malaria. The latter was found among the heroin addicts who used the intravenous route and has been completely described by Dr. Milton Helpern. This patient had employed the subcutaneous route during the past eight months, which would be an unlikely cause for vegetative endocarditis. He may have reverted periodically to the intravenous injections. The distribution of the systolic murmur over the precordium suggests that the aortic cusps were involved. The state of the valve cusps at autopsy should give us a better clue as to the duration of the present illness and whether it was superimposed on an old inflammatory or congenital bicuspid valve. The patient complained of pain over his left chest, which apparently was not due to pneumonia. The aortic vegetations have a tendency to break through to the pericardium, but no mention was made of a pericardial rub. Pericarditis can cause pain over the precordium. Death was due seemingly to sepsis and to circulatory collapse. With the aortic site of the vegetation, we have the possibility of a coronary embolism hastening death. Although auricular fibrillation rarely precedes the occurrence of subacute bacterial endocarditis, it may occur as a late manifestation.

MAJOR LOUIS F. BISHOP, U.S.A.: In this case the differential diagnosis lies between subacute and acute bacterial endocarditis.

There was no evidence that this patient had an endocarditis for a long time. The spleen was not palpable; there was no anemia, and no embolic phenomena were noted. I believe we will find an acute vegetative endocarditis. Although it is unusual for Str. viridans to be the causative agent, I believe this is an acute endocarditis due to Str. viridans superimposed on an old rheumatic heart. In the Army, we find many apparen healthy young men with aortic diastolic mu murs who never have shown any symptoms cardiac damage and whose hearts are not l larged. It is possible that they may ha damaged valves, and such a valve would be likely seat for subsequent bacterial endocardit

DR. HARRY A. SOLOMON: This case is pr sented as acute bacterial endocarditis due Str. viridans. As in other types of acute ba terial endocarditis, the positive blood cultu gave the first indication of the diagnosis befo the characteristic features of the subacute typ such as embolic phenomena, had a chance develop.

There has been a tendency recently to con sider the Str. viridans as a nonpathogen secondary invader in subacute bacterial endo carditis, but even in these fulminating cases w have never been able to demonstrate a mixed in fection.

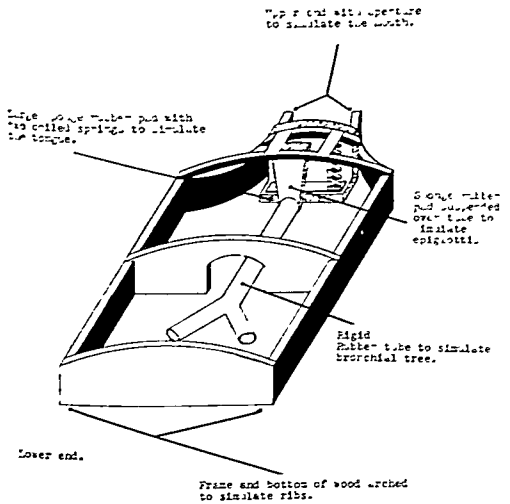
With the predominant involvement on the aortic valve and with symptoms indicating rapid development of heart failure and an overwhelming toxic state, one might be justified in suggesting the possibility that the vegetations had extended into the coronary vessels.

Necrosis of the cusps could account for the changing aortic murmur, and extensive myocardial infarction would account for the sudden heart failure and increased toxic state. These serious developments of the disease itself would probably have been attributed to the sulfonamides effect if the contemplated therapy had been carried out beforehand.

DR. TRUBEK: In a clinical case of bacterial endocarditis, the finding of Str. viridans in the blood culture cannot be regarded as a so-called secondary invader. Such a phenomenon might occur during other illnesses, such as typhoid fever, where the Str. non-haemolyticus may eventually invade the blood stream of the patient, who is debilitated by the primary major illness.

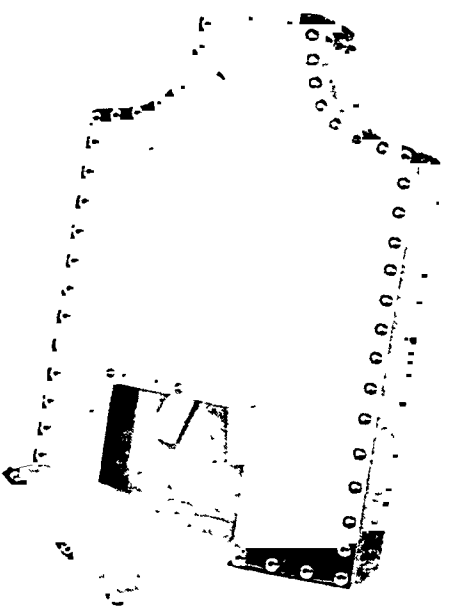
DR. ARNOLD KOFFLER: There are a few interesting features in this case that I should like to discuss. In the first place, I should like to point out the similarity in symptomatology between subacute bacterial endocarditis and pulmonary tuberculosis. The hacking cough, spiking temperature, weakness, and sweating may easily be mistaken for, or confused with, tuberculosis. The cough in the early case of endocarditis is difficult to explain, but it has been suggested that it may be due to enlargement of the tracheobronchial glands.

The pathology in this case points particularly to the aortic valve where the commonest causes of involvement are due to rheumatic infection



A BRONCHOSCOPIC MANIKIN

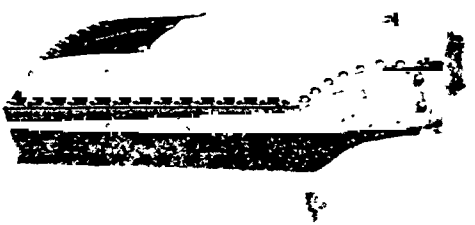
GERVAIS WARD MCAULIFFE, M.D., New York City



THE USE of a laryngoscope, bronchoscope, or an esophagoscope is a technical procedure which requires considerable skill. The comparative ease with which a larynx can be injured or an esophagus perforated by an untrained operator constitutes the major barrier to a more general use of this form of examination. Training in the use of these instruments should begin with a comprehensive review of the anatomy of the upper respiratory tract. Emphasis should be placed on the natural barriers or anatomic obstructions that make examination of the larynx, bronchi, or the esophagus difficult. The initial training should begin with a manikin, the student then advancing to work on a cadaver and a dog before attempting to work on the human being.

We devised the manikin here illustrated in order to place particular emphasis on the main anatomic obstructions which have to be overcome before a clear delineation of the larynx, bronchi, or esophagus can be obtained with a laryngoscope, bronchoscope, or an esophagoscope.

In actual use the manikin has proved helpful and it is inexpensive to assemble.



A bronchoscopic manikin

Side view

were prominent because of moderate deposits of fibrous tissue and aggregates of lymphocytes. None of these deposits communicated with each other. Sections of the spleen showed considerable hyperplasia of the red pulp, with increase in mononuclear and polynuclear cells. The Malpighian corpuscles were large but otherwise not remarkable.

Sections of the kidneys disclosed no unusual changes and no focal embolic lesions were encountered in the glomeruli.

Postmortem cultures of the vegetations on the aortic valve yielded a pure growth of Str. viridans.

Pathologic Diagnoses

Subacute bacterial endocarditis (Str. viridans) of the bicuspid aortic valve with extension via the root of the aorta to the right auricle and to the epicardium.
Mycotic aneurysms of the sinuses of Valsalva.
Polypoid vegetative endocarditis of the right auricle.
Hypertropy and dilatation of heart, chiefly of the left ventricle.
Acute fibrinopurulent pericarditis.
Pulp hyperplasia of spleen.
Mild chronic passive congestion of liver.
Mild portal cirrhosis of liver.

Comments

This case furnished a number of points for comment. The first is the nature of the underlying aortic lesion on which bacterial endocarditis was superimposed. It was demonstrated that the aortic cusps had fibrous and calcific centers beneath the vegetation, but the process was so advanced as to preclude a definite diagnosis of the antecedent status. The destruction of the raphe behind the large cusp limited the analysis in a similar way.

There are three general categories of bicuspid aortic valve which are generally recognized. The *congenital* does not seem to apply since the cusps were of unequal size. The *rheumatic* type in which two cusps become fused as a result of inflammation seems to be excluded because of the absence of rheumatic stigmata in other parts of the heart. The third category, commonly encountered in the form of *calcareous disease* of the aortic valve, is of doubtful etiology itself, with some authorities insisting that it represents the end stage of old endocarditis, whether rheumatic or of other cause. Others hold it to be an independent degenerative lesion of the aortic leaflets which may lead to the acquired bicuspid state by fusion of adjacent heavily involved cusps.

In the absence of rheumatic signs in other parts of the heart, one is tempted to place this case in the third category, but since rheumatic fever occasionally affects the aortic leaflets alone and only a few blocks were taken from other parts of the heart, we cannot be dogmatic about the classification of this heart.

The terminal disturbances in electrical conduction may be correlated with the strategic location of the mycotic aneurysm and its extension to the myocardium and into the auricle wall. This probably accounts for the prolonged auriculoventricular conduction and the sudden development of auricular fibrillation. I suspect that the sudden death accompanied by convulsive movements may be on the basis of complete heart block.

Finally, this case illustrates the difficulty of correlating acute symptoms in life with progressive morphologic changes that may be below the level of clinical detection. The short duration of the patient's symptoms are out of all proportion to the obviously advanced degenerative and inflammatory changes in the heart. While the course was relatively acute clinically, the morphologic changes reflect a much longer process.

SPECIAL SCHOOL TO STUDY ALCOHOLISM

The first formal school in the academic history of the United States to study the consequences of alcohol is being held in a six-week session of a School of Alcohol Studies at Yale University this summer.

Sponsored by the scientists of the Yale Laboratory of Applied Physiology, of which Professor Howard W. Haggard is director, it has enrolled about seventy-five educators, social workers, clergymen, and enforcement officers.

"The prevention of alcoholism and its ill effects is hampered by the lack of community leaders who have a broad scientific understanding of the problems of alcohol," the school prospectus said. "The aim of the school is to educate such leaders by giving them thorough grounding in scientific knowledge about these problems."

The School opened July 8, directed by Dr. E. M. Jellinek of the Yale Laboratory of Applied Psychology, and will continue through Aug. 18.

Groups cooperating are the National Education Association and the Federal Council of Churches of Christ in America. Each has agreed to assist in the selection of students for fellowship grants and to interpret the purposes of the school to the professional field in which it operates.

f Health, New York City: Agglutinates in O antigen of typhoid 1:20 dilution; negative for paratyphoid A and B; negative for Brucella; negative for typhus. A routine urine examination was negative. The blood count showed: hemoglobin, 76.6 per cent; red blood count, 3,930,000; white blood count, 11,600; polymorphonuclears, 86 per cent; and lymphocytes, 14 per cent.

On the twenty-second postoperative day, the patient developed a marked stomatitis. Smears for Vincent's organism were negative. Agglutination for typhus was also negative. Blood count: hemoglobin, 80 per cent; red blood count, 4,310,000; white blood count, 9,000; polymorphonuclears, 85 per cent; mononuclears, 1 per cent; lymphocytes, 13 per cent; and Türk cells, 1 per cent.

On the twenty-third postoperative day, the temperature reached 101 F. and was normal on the following day, remaining normal until the patient was discharged from the hospital, thirty-two days after the operation.

The chest cleared, and the stomatitis subsided. The spleen was at no time palpable. Urine culture from the Department of Health, New York City, was positive for Brucella. The only medication given was sulfadiazine.

Comment

The patient became infected by drinking goat's milk. His occupation as a mortician, in which he handled bodies, particularly Italian in nationality, must also be given thought. An individual who has been infected with the Brucella organism may apparently be in good health. The precipitation of the symptomatology of acute brucellosis is by a surgical procedure.

Conclusions

A case of chronic brucellosis has been presented. The final diagnosis of the disease rests with the isolation of the organism. The clinical picture of an acute type can be associated with a surgical procedure. Brucellosis must be thought of in postoperative continued pyrexia.

CONSTITUTIONAL INADEQUACY

"The main trouble with many of the patients that I see every day is that they are always weak and tired and full of pains and always getting sick in one way or another. Many have been operated on several times, but still they aren't well and they cannot get about and have fun as other people do.

"Again and again these patients go to some consultant or medical institution with the idea that this time they will get examined so thoroughly that the cause of all their troubles will be found and perhaps removed. Again and again they get overhauled, and each time the physician finds some little abnormality or physical peculiarity which he views with alarm and treats for a while.

"Commonest among the diagnoses made nowadays in the hope of explaining the sufferings of these people are colitis, spastic colon, ptosis, pelvic disease, adhesions, chronic appendicitis, glandular dysfunction, low blood pressure, mild Addison's disease, low blood calcium, brucellosis, and chronic nervous exhaustion. That in a given case the diagnoses made in the past were wrong and the local abnormalities found were not sufficient to explain the illness can be seen from one fact alone, and this is that the extensive treatments carried out and the operations performed in an effort to correct the supposed diseases did not put an end to the symptoms."

In the above paragraphs Alvarez admirably and succinctly sums up the problem of how best to deal with these people. Alvarez holds that it is incumbent upon the profession to recognize these individuals promptly, when they first begin to crack up, and that "when we do recognize the functional nature of the syndrome we must not rest satisfied with the diagnosis of chronic nervous exhaustion, as so many of us are now inclined to do, but must go on to apply a label—constitutional inadequacy—which will keep reminding us that we are dealing with an inborn and essentially ineradicable disease."

The Rochester clinician believes that "whatever the cause of this protean syndrome is, I am sure it is not to be found in any disease in any one organ, unless it is the brain. Actually, in most cases I feel sure the primary constitutional weakness is in the nervous system." And also that "the main defect in the inadequate person seems often to be a lack of that something in the brain that keeps most persons feeling well and unconcerned about health."

Alvarez believes that "constitutional inadequacy is inherited from forebears who suffered either from inadequacy, frailness of body, poor pituitary development, or some form of psychopathy." And we are also told that "treatment must consist mainly of keeping the patients from doing foolish things and wasting money. They must be taught, if possible, to acquiesce to the situation, to stop hunting for a complete cure, to hoard their energies, and to find a job that can be done without too much fatigue.

"In times of war every effort must be made to keep the constitutionally inadequate out of the Army.

"All they do is to break down morale and go on the pension roll."

Though his article is brief, the Rochester investigator has managed to cover a difficult subject well and in a convincing manner. Apparently the constitutionally inferior will be with us for a long time and every practitioner must strive to recognize them promptly and then endeavor to deal with them in the best possible manner. The recognition and proper evaluation of the functional disorders is especially deficient in students, interns, and very young doctors, though many older physicians fail all too often in this respect also. Handling these patients is apt to be difficult in the extreme and calls for much tact, sympathy, and understanding as well as diagnostic acumen and therapeutic proficiency.—*Editorial, J.M.A. State of Alabama*

Case Report

AN UNUSUAL CASE OF UNDULANT FEVER WITH POSTOPERATIVE PYREXIA

MILTON H. MORRIS, M.D., Far Rockaway, New York

Etiologic Review

With the recognition of undulant fever by Marston and the description of its causative agent by Bruce, the epidemiology of the disease has required considerable investigation and study.

Craig described the first case in the United States, and its endemic nature was recognized by Ferenbaugh, in Texas, who described an epidemic of 331 cases. This was followed by the designation of undulant fever as a reportable disease.

The occurrence of undulant fever among employees of packing houses has been described, but in a series of 270 cases only 4 could be traced to this source. Over 80 per cent of the cases are associated with the drinking of raw goat's milk. There have been cases described in which other domestic animals were the source of infection—namely, horses, mules, dogs, rabbits, and poultry. These animals are not, however, the reservoirs of infection and are not directly associated with its spread.

The ingestion of uncooked meat, such as liver and sausages, has been described as the cause of the disease. The spread by human carriers and by patients with chronic brucellosis, who are asymptomatic, is another way of propagating undulant fever, although to a small degree. It is recognized that 10 per cent of the cases do not have acute episodes but complain only of ill health, the cardinal symptoms of which are weakness and low-grade fever, and present no physical signs of the disease.

The occurrence of a water-borne epidemic among laboratory workers and the personnel, in which 80 cases occurred, was reported by Drs. A. W. Newwith, T. M. Koppa, and D. W. Gudakunst, from Michigan State College.*

The disease can also be contracted by handling discharges of the aborted fetus and its membranes.

Experimentally, the disease has been transmitted to the monkey by the bite of a mosquito. This, however, has not been demonstrated in man.

The most important animal in the spread of the disease in man is the goat, the primary host. It has been shown that man is more susceptible to the organism of the goat than he is to that of the cow or pig.

I present the following case of undulant fever, occurring in an individual who has never had the disease clinically, and who, following a surgical procedure, developed the clinical disease, acute brucellosis, with confirmatory laboratory findings.

Case Report

A 35-year-old white man, a mortician by occupation, entered St. Joseph's Hospital, Far Rockaway, New York, for an operation for inguinal hernia. The hernia was repaired in the usual surgical manner with no undue incidents during the operation. The pathologist's report of the hernial sac was that of fibrous and fatty tissue.

The patient's temperature was normal for seven days, but on the eighth day it rose to 104.6 F. The respirations were slightly increased, and the pulse rose to 100. The fever continued for seven days, the temperature fluctuating one or two degrees. On the fifteenth day postoperatively, the temperature reached normal and remained normal for three days. It then rose gradually to 104 F. and with fluctuations remained elevated for five days, dropped to normal, and remained so for the duration of the patient's stay in the hospital. He was discharged thirty-two days postoperatively.

Clinical Course.—The most important fact in the history is that, after questioning, the patient admitted drinking goat's milk about five years before, but at no time during this period was he sick or did he complain of ill health.

His physical examination was negative except for the presence of a right inguinal hernia. Urine was negative. A blood count was as follows: hemoglobin, 9.3 per cent; red blood count, 4,570,000; white blood count, 7,308; polymorphonuclears, 72 per cent; and lymphocytes, 28 per cent.

The patient was well until the eighth postoperative day. His temperature then reached 104.6 F., and he complained of a severe headache. Surgical consultation was negative. Physical examination was negative. The wound was dressed and cleaned, and there was a primary union. Ear, nose, and throat consultation was negative. Urine was negative. The diazo reaction was negative. The blood count: hemoglobin 86.5 per cent; red blood count, 4,470,000; white blood count, 5,900; polymorphonuclears, 82 per cent; lymphocytes, 17 per cent; and mononuclears, 1 per cent.

The blood Widal test was negative. Blood agglutination was negative for paratyphoid, A and B; stool culture was negative for typhoid, paratyphoid, and dysentery. Blood culture showed no growth in ninety-six hours. Urine culture showed: (1) pseudodiphtheria and (2) gram-negative small ovoid rods having the morphology and cultural characteristics of Br. melitensis. The report from the Department of Health was as follows: Brucella melitensis agglutinated in serum dilutions 1:80.

The temperature followed the course that has already been described. An x-ray on the seventeenth postoperative day revealed no pathology. On the twentieth postoperative day, the patient complained of severe pain in the right chest. Physical findings revealed some sonorous rales posteriorly above the fourth rib on the right side. Below this area, breath sounds were diminished. The x-ray report showed a marked thickening of the pleura and a trace of fluid in the costophrenic sulcus. A few mottled shadows were present in the mesial portion of the left lower lobe. The right dome of the diaphragm was obscured by pleuritis.

On the twenty-first postoperative day, the following report of blood was given by the Department

* Newwith, A. W., Koppa, T. M., and Gudakunst, D. W.; Am. J. Pub. Health, 29: 739–743 (July) 1939.

laborationists saved Paris, but who knows what will happen to Paris and all the other occupied places before the enemy leaves?

Restoration is the first work before anything else can be set up. Industry must be started, trade begun again, and transportation put in order. Employment must be found. We will have to do a large part of that unless we want to live in a world of corpses.

Then after that, what? After that, the beginning of cooperation. Cooperation will form itself by reason of necessity. The victorious nations will have to establish and maintain order in the world by reason of the conditions which will confront them. That cooperation will lead to something else. It will finally gather together the nucleus of a new order to maintain the peace which has been won.

And now I speak of what is very, very dominant and very important to you all and to all the people who want peace. I have read all the speeches; I have read Vice-President Wallace's speeches; I have read Mr. Willkie's speeches; I have examined the reports of groups which are studying the new world organization, and I do not find in them an examination of the cause for the failure of the League of Nations.

It would seem reasonable, would it not, that when we have had examples before us of efforts to maintain peace and to organize states in combination, that we should examine those organizations to find out why they fail, and then, having found out why they have failed, to see if we can apply a cure that will make them work?

They say—and I speak of the scoffers, and the timid, and the unbelievers, and the doubters—'How can it ever work? How can any world organization ever work in view of human frailties, of the competition and jealousies of nations, of the inimical force of politics, and of the ambitions of rulers and of politicians? How can it ever be made to work?"

If those who establish the postwar organization follow the old League lines, if they follow the old methods of attempted national cooperation, if they follow the plans that seem to be now in contemplation, they are bound to fail—and that in a very short time. The reason they are bound to fail is because of the very structure of such combinations of states or nations. Let us examine two examples.

We had in this country a United States of America before our own was organized. It was called "the Confederation." It was composed, as you know, of the Thirteen Colonies. They were combined in a League, in a United States, but they lasted only eight years. Why did they fail?

It was interesting to me, having worked on this problem on my own account, to find that I had support in very high quarters; and that support comes from Alexander Hamilton. Hamilton told the colonies why they failed, and what the cure was. It was not a people's league; it was a league of states. This is what Hamilton had to say on the subject: "The great and radical vice in the construction of the existing Confederation is the principle of legislation for states or governments in their corporate or collective capacity as contradistinguished from the individuals of which they consist." This was the defect, and in the Constitutional Convention they found the cure and formed a more perfect union.

If you smuggled something into the Port of New York under this new and better union that was formed, and should say to the customs officers, "I am a resident of the State of Massachusetts. I appeal to the State of Massachusetts," it would not do you any good. Why? Because the twenty powers given to the Central government of the United States are controls over individuals. You, as an individual, are brought up before the court, not as a member of a state. The government deals directly with you as an individual. When the constitution of the United States was established it did not say, "We, the thirteen colonies," or "We, the thirteen states," or "We, the thirteen nations." No, it proclaimed, "We, the People." We, the People, have organized this government to establish justice. And so it must be with any league of nations if it is to endure.

We are held together here by what I call an impersonal concept: our love of justice and our love of freedom, which thrills in every American heart. You have an impersonal concept in your Medical Society that binds you together in unity: your individual obligation to the whole, as individuals. If you are going to have peace in the world, you must have an organization or a government of peoples having in their hearts the concept, "We will no longer submit to being destroyed by war. We will set up a body of law which will say 'This thou shalt not do because it leads to war,'" and so we pass from the field of diplomacy into the sphere of law, and have a hope for life.

The League had its chance and what happened? The first opportunity was with Manchuria and Japan. Japan marched into that country without any just reason, yet the League did not even attempt to apply sanctions. Nations could not agree just as the colonies could not agree. They had been brought to disaster because each colony was first for itself and the devil take the hindmost.

Then came Italy and Abyssinia. Now the theory of the League was plain enough. These sanctions were: First, sever all diplomatic relations; second, sever all commercial relations; these would bring any country to its knees at once.

What happened? The traitor, Laval, went to Italy, and he came back with a formula, "easy sanctions gradually applied." That suited many interests in several countries, and they went on selling to Italy what she needed. Although we were not a member of the League, we could have done something, but we kept on selling them oil. The Italians went over to Africa, and they did not have a war; they just burned up the poor Abyssinians with their poison gas, and charred corpses were strewn over the desert, while the peoples of the world said, "The League has lost its authority! Are these traitors more important than this organization which we have set up to maintain peace in the world? Are these traitors going to abandon the effort until war is upon us again?" Well, the war is again upon us, and here we are in the midst of it.

It is said that if the United States had gone into the League this would not have happened. We could have taken part without being in it; and it did happen. Is our government so superior? Are our representatives so exalted in their ideas and their ethics? Are we so willing to make sacrifices for the common good and peace of the world?

It is said that if the League had had teeth it would have succeeded. Let me tell you what happened. The League would not even apply the commercial sanctions which were provided. Do you think they would have applied military sanctions, which is what "teeth" means? If they had been there, would they have gone to war with Italy when they would not stop trading with her? Certainly not. This claim that if they had had teeth in the League it

Annual Meeting

Medical Society of the State of New York

FOLLOWING the president's Address, which appeared in the June 1 issue of the JOURNAL, President Cottis introduced the guest speaker of the meeting.

Address

JUDGE WILLIAM H. WADHAMS

Mr. President, Ladies and Gentlemen: Doctors of Medicine are the fighters of death and the conservers of health. You look into the eyes of men and women throughout this state, and you learn their innermost thoughts, and you have glimpses into their souls. You know that these people are determined, first, to win the victory over the enemies we are now engaging, and then by some method to see to it that this fatal disease, this terrible calamity of war, which from time to time inflicts mankind, shall not continue in the world. You work to save lives, yet one bombardment of one city by four-ton blockbusters kills more people in an instant than you could save in a hundred years.

The tragedy is great. The remedy must be severe, and it must be applied. I was holding court in New York, when the messenger came in and said, "Armistice! Armistice! Armistice has been signed today." The court adjourned, and everyone rushed into the streets. The war was over, the killing was finished, our boys were coming home, peace reigned again in the world. We formed a procession. We marched up Broadway. The people all came out of their offices, and they fell into each other's arms. There was dancing and rejoicing, for the war to end wars had been won. It was going to be a new and a better world, and we were going to have peace on earth and good will among men.

Some of us had been working on a proposition as to how to bring that about. We had an organization called "The League to Enforce Peace." Ex-President Taft was its president and Lawrence Lowell, of Harvard, was the chairman of its executive committee. We formed a committee to organize a plan, and we drafted what we called a League of Nations. We went about talking about it. There was a pretty general approval, and we had a great dinner in Washington at which the heads of all the elements in the United States, the clergy, the leaders of industry and of labor, the doctors, the lawyers, the professions, and all classes and conditions of men were present. This program which we had prepared was presented to President Wilson, and he adopted it, and worked on it, and took it over to Paris with him. There had been some modifications in it; the teeth had been drawn. I had the privilege of being in the Clock Room at the Quay d'Orsay when he presented it to the Peace Conference in the form of the Covenant of the League of Nations. The delegates and the ambassadors could only take in one guest apiece, and I had the good fortune to be taken by our Ambassador as his secretary; so I clung to his coattails, and found myself sitting next to Orlando of Italy on the one hand and Jules Cambon of France on the other.

As President Wilson arose slowly and solemnly, he seemed to look into the future, offering peace to mankind through his League. There was a moment when it appeared that he was the savior of men, for all the peoples of the world were longing for peace. When he had finished reading, there were many speeches of approval. However, as he sat down, after reading the Covenant, Clemenceau, the lion of France, who had done such wonders in the World War but who had no peace vision for the future, turned around and looked at Cambon, who was sitting beside me, and winked. That wink told the whole story of the future of the League of Nations.

Having an office abroad, I had the opportunity to follow the League's course, and to see its failure and collapse. Let us hold an autopsy. What was the cause of the death of the League? An autopsy is only valuable for another patient, in case we find out how we can apply the reasons of death that we have discovered. The cause of the death of the League was that it was not a people's league; it was a government's league. It was a league of diplomacy. The Covenant was as good an instrument for the expression by a League of Nations of the common and unanimous will of the governments of its members as could well be drawn, yet it failed.

Before we go further and investigate what were the defects of its provisions and what may be a cure, I wish to warn you that the establishment of peace is not a thing that can be done overnight. First the victory must be won, and nothing must divert our attention from winning that victory, because until the aggressor has been vanquished there can be no peace. There can be no peace until we have utterly routed a people who have been educated to believe that hate is a virtue and that war is a normal condition. After the victory we will have to clear up the ruins—and such ruins as have never been contemplated. There are no kitchen utensils left for the women in their kitchens in France. The leather has been torn from the chairs, and the sofas, everything that is movable, everything that they can lay their hands on, the Germans have carted off to Germany, including my library; and the last I heard the Frigidaire had also gone after the library. Factories are gutted, the machinery is gone, and that which is there is being used to the utmost and will be worn out and valueless. The populations are being removed and scattered over the face of the globe. Children are being sent apart from their parents to unknown places, and their names changed. The mere work of trying to gather together the scattered remnants of what lives is in itself a tremendous task. Epidemics and starvation such as have never been known threaten the peoples of the world, starvation that looks for a crumb of bread. The Germans have not left these countries yet, and I tremble to think of what they will do before they leave them. Col-

Delivered at the 137th Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

or, if sailing on the sea, in fear that the unseen submarine may destroy them. All the peoples long for freedom from fear, freedom from the fear of the monsters of the world, freedom from fear of the education of hate and war.

How are we going to stop this insane horror? By control of those who make the wars; by control of those who make the machinery of war. Everybody is agreed that we must stop this business of building these terrible instruments of destruction. But don't think we can stop it by acting through governments. History shows we cannot. But we can stop it by acting through law. Let me give you an example.

Supposing at some future time some future Mr. Goering started manufacturing arms and that it is against the law of nations for anyone to manufacture arms unless he has a licen e from the League created to see to it that the people shall have peace. Under the old league form, the Council of the League would pass a resolution, and through its diplomatic channels would address the government in which Mr. Goering lived. That Government would say, "Thank you very much! We will make an investigation." Perhaps weeks, or more likely, months later, would come a reply to the League, "We have investigated this matter very carefully, and we regret to say we find a grievous error has been committed. Mr. Goering is not manufacturing arms; he is manufacturing agricultural machinery."

What are we going to do about it? If we reject the reply of the government in which Mr. Goering lives, we are attacking his nation. We are promoting a crisis, which, if Mr. Goering persists, can only be overcome by force; and that means war.

What is the other alternative? The other alternative is to do what they did in the case of Italy: Swallow our pride, forget it, let Mr. Goering go on manufacturing arms and build up his war machinery, as well as other Mr. Goerings, until again the flame of war bursts upon the world; and so our league has also failed, whichever course it pursues.

Now supposing you had a real people's government, a League which pursuant to law had power to arrest individuals who violated its laws. The military police would swoop down in an airplane, arrest Mr. Goering, and take him to the nearest court, where he would be tried. It would be his offense, not the offense of the country in which he lives. Such a League deals directly with the individual, the individual who is stopped from doing the forbidden act. All acts of government, or of corporations, or of companies are performed by individuals. That is the way we stop crimes in the United States. As you know, there are only about twenty powers that by the Federal Constitution are given to the Federal Government, and they are all to prevent disobedience by individuals. To obtain freedom from fear we must stop armaments. We never will stop the production of armaments by nations through treaties, pacts, or agreements, or through any league based upon such foundations: but we can stop such production immediately, by League action against the individual.

That will give us freedom from fear. And now we come to freedom from want. I am reminded of something that concerned this City of Buffalo. At one time I was counsel for the New York Produce Exchange. We looked upon the Great Lakes, and found no boats were moving on them. The Great Lakes had dried up. And why? Because the railroads had made the freight rate from the foot of the Lakes, from Buffalo and Erie to Boston, New York, and Philadelphia so high that they had forced all freight to come all rail from the West, thereby depriving the shipper of cheap transportation on the Lakes. I went before the Interstate Commerce Commission and presented the case, and they changed the rate and made it a reasonable rate from the foot of the Great Lakes to the Atlantic Seaboard, and the boats began to move again on the Great Lakes. To do that, I did not bring in the State of Illinois, I did not bring in the State of New York, or the State of Ohio, or the State of Massachusetts. No, I brought in the railroads; the individuals had to obey the order of the court.

To ensure freedom from want, control transportation and trade so that the raw materials may go where they are absolutely needed, and so that there may not be great congestions of produce burned up in one spot while people are starving in other places; prevent the suffering and distress that cause new wars; bring the steamship companies into court. We will never obtain freedom from want by relying upon the voluntary actions of national governments.

Freedom of the press and the freedom of speech may be protected in the same way by requiring individual obedience to protecting laws. Any man who is oppressed ought to have a chance to be heard. At present there is no international court where he may apply for protection. There was no international bill of rights.

As nearly as we have come to it so far, the Four Freedoms and those expressed in the Atlantic Charter are a draft of the bill of rights. That is what the people are longing for because it contains in it the rights that man must have if he is to enjoy peace and freedom. Therefore, it is our obligation to see to it that this is a government of the peoples with responsibility of the people to obey. We made this government a government of laws, and not of men. That has been the trouble with France. France collapsed because it has been a government of men. They followed their leaders in the French Revolution. Then they followed the glory of Napoleon. Now some of them followed Vichy and its leaders. They were divided into factions, and they were working for one purpose—for themselves, not for France. They had no moral force to hold them together. The motto of the French Government, "Liberty, Equality and Fraternity," was mere words, a slogan. No, there was no unity in France; and if we are going to have peace in the world we have got to have unity in our people, a unity insisting that the people obtain a real organization of law to maintain peace.

Listen and watch. Listen to the speeches. Watch the proposals. See what speakers are talking about—whether they are talking about boundaries, or about big and little countries, or about forms of government, or about regional groupings. If you have a law of nations, it does not make any difference whether you live this side or the other side of a boundary; you are bound to obey the law. The boundary line is no obstacle to putting in such a plan. There is no objection to regional groupings, Pan-American Unions, the Danubian Union, or even a United States of Europe, providing all the citizens, the nations of such unions, are also bound to obey the Law of Nations to preserve peace. It does not make so much difference what the form of the government of each nation is, much as we would like to promote the democratic idea. Whether you are living under the Common Law of England in Massachusetts or under the Code Napoleon in Louisiana, it makes no difference; you are bound by that cen-

would have succeeded is sheer nonsense. There is something much more serious the matter with the League than that. It is the basic principle of such an organization that counts. There was a fundamental defect in the League's structure.

You can examine all the national and international combines, and you will find that if this defect is present, they, all of them, fail; and when it is not present, they succeed. That is why all the leagues that have been formed upon the personal obligation principle, dealing directly with the individual, have succeeded, and when they rely upon nation dealing with nation they do not succeed.

And why not? It is because of the virtue of nations. I repeat—the virtue of nations. A nation has been a very useful thing in the organization of mankind, but what is the duty of those in charge of a nation? To make the nation the most powerful, the richest, and the greatest country in the world. We hear a lot of that here. We enjoy waving the flag and letting the eagle scream. The duty of those in charge of a nation is to protect and promote the interests of its individuals. Very good! That is a very noble virtue, yet in the hands of foreign offices, state departments, and government agencies it immediately blocks any cooperation by a league because all the others are thinking the same thing. They are thus bound to come into conflict, and it is impossible for them in the nature of things to agree. History proves it. Legislation by a league is merely a proposal. It has to go back to the nations that form the league, and then in order to get it adopted you have to persuade them. You have to persuade them through diplomatic channels. The proposal is referred through its foreign office to a careful executive and to a jealous legislative body and to a debating committee, and in the meantime the aggression goes on, and the countries take sides, and the war proceeds. This is the inevitable result of the formation of a league along the old lines. It does not deal directly with the individual; it deals only with governments. Governments need take no affirmative act to defeat the league plan. All they have to do is to sit down and do nothing, or, as in the case of Italy, present an evasive plan.

When you consider what is at stake you will realize the importance of a proper foundation for any new order. How are they going about it now? Are they going along the old league lines that always fail? How are they thinking now? The old League had a general mandate to maintain peace based upon treaties between the nations.

The new league, whatever it is, will have definite and limited powers enforceable by law. What will those powers have to be? We have heard about the Four Freedoms. We know that the Four Freedoms are a glorious thing to have. Are you going to rely upon moral suasion to get them? If so, you will join the ranks of the wishful thinkers who are expecting by their wishfulness to obtain peace in the world. If you don't get them by moral suasion, are you going to get them by treaties, pacts, agreements among nations? The mere mention of the Kellogg Pacts raises hilarious and bitter laughter! War was banished by those pacts. Who forgot that? Are you going to rely upon balances of power? The trouble with power is that it does not remain balanced. The very conception of a balance of power is the antithesis of peace for the reason that by balancing power you are building up strength just as the German strength was built up to balance power in Europe, and when one of the parties obtains the upper hand, and the government is in the hands of ruthless, and determined, and ambitious leaders, your balance of power leads inevitably to war.

A league has to act through persuasion, and how are you going to do the persuading? A country's agents, of whatever party or whoever they are, who undertake to carry out a resolution of a league which is apparently a disadvantage—a temporary disadvantage—to their country, would have no chance of success. A jingo press would make it immediately perfectly clear to everyone that it would be an outrage for the nation to go forward along the lines of the league's resolution. It would be easy to create a national clamor, a national demand to break away from the league. That is what Lord Bryce pointed out. He said, "There are two kinds of leagues." One is "A league in which a number of political bodies, be they monarchies or republics, are bound together so as to constitute for certain purposes, and especially for the purpose of common defense, a single body. The members of such a composite body or League are not individual men but communities. It exists only as an aggregate of communities and will therefore vanish as soon as the communities which compose it separate themselves from one another. Moreover, it deals with and acts upon these communities only. With the individual it has nothing to do."

Such is the structure of leagues which, like the League of Nations, fail to maintain peace. As Lord Bryce says, they *vanish*. The second form of leagues, those which succeed, is a union of the people of nations which compose it. It does not deal through the government of those nations, but directly with their citizens, demanding individual obedience to its laws.

There is no use in blinding our eyes to the situation. It is not that I am condemning governments or their agents. They do the best they can even when they are in the hands of devious politicians and ambitious men. They do the best they can, and it is human nature that they should, because otherwise they would not remain in office; they cannot resist organized pressure and the people are unorganized. The people cannot express themselves sufficiently clearly, promptly, and energetically enough to prevent the acts which produce wars. We did not want this war. We did not cause it. We did not enter upon it because we were after anything in the world. We had to go into it to defend ourselves. We know that. But we are looking forward to other aggressors in the future who, like this arch fiend of hell, may put all the world into the devouring jaws of death. We have the power to prevent it, but only if you really want to prevent war. Are you really enthusiastic enough for freedom? We give our money, we give our sons, we give our people, we give everything for war; but what are we willing to give for peace? How much peace could we have bought with what we have expended? What years of millennium could have been purchased with this enormous waste of billions of dollars and millions of men?

Do we really want peace? Then organize for it. We, the people, we insist upon a government of law; we insist upon establishing a league that will assure us the Four Freedoms by giving it the necessary power over individual violations of its laws. I have not the time to discuss these laws with you. However, I will mention some examples. One of them concerns freedom from fear. We all live in fear. We don't know when a bomb is coming here. Those who live in the war-stricken areas are momentarily in fear of bombs that may be dropped from the skies,

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. *The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.*

Revised Course Outline Book

THE Council Committee on Public Health and Education will soon have ready for distribution the revised *Course Outline Book* announcing the programs available for postgraduate medical education.

This instruction will be provided for county medical societies and hospital staffs.

Many new programs have been added and the already broad scope of subjects has been considerably increased. One interesting and timely addition is the "Teaching Day on Poliomyelitis." This presentation is divided into four parts:

1. Epidemiology of Poliomyelitis.—The scientific knowledge of this subject will be reviewed and brought up to date and special consideration will be given to more recently developed concepts, such as tonsillectomy and adenoidectomy as precipitating factors, and the role of sewage as a possible factor in transmission.
2. Clinical Features—Pathology, Diagnosis, and General Treatment.—All aspects of this subject will be reviewed. The newer work on the spread of the virus in the body and its possible clinical significance will be discussed. The question of the role of the respirator in therapy will be considered.
3. Physical Therapy in the Acute and Convalescent Stages.—Particular emphasis will be given to the Kenny Method. The significance of muscle spasm in the clinical picture of poliomyelitis will be discussed, the technic of detecting it will be described, and currently accepted recommendations regarding the extent and duration of the hot-pack treatment will be outlined. The accepted principles and technic of muscle re-education will be discussed.
4. Orthopaedic Measures.—The prevention of deformity by reduction of muscle spasm and by control of muscle imbalance will be considered. The current status of rehabilitative procedures (muscle re-education and other physical therapy) and of reconstructive and stabilizing surgery in the residual stage will be discussed.

Copies of the *Course Outline Book* will be sent to officers and committee chairmen of each county medical society. Also, copies may be obtained by others interested in postgraduate medical education by writing to:

O. W. H. MITCHELL, M.D., *Chairman*, Council Committee on Public Health and Education
428 Greenwood Place, Syracuse 10, New York

Malone Hospital Staff Hears Lecture on Rheumatic Disease

A SINGLE lecture, arranged for a staff meeting of the Alice Hyde Memorial Hospital in Malone, was held on July 20 at the Elk's Club in that city.

Dr. J. G. Fred Hiss, professor of clinical medicine at the University of Syracuse College of Medicine, spoke on "Rheumatic Fever—Rheumatic Heart Disease."

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the New York State Department of Health.

COLUMBIA GIVES COURSES IN THERAPY

Among the special courses being offered by Columbia University to prepare personnel for immediate and postwar rehabilitation are two professional programs—physical therapy and occupational therapy.

Technicians in both of these fields are in urgent demand in the Army and Navy as well as in the civilian field. Both of these specialized programs are designed to meet the requirements specified by the Council on Medical Education and Hospitals of the American Medical Association and are conducted within the University in close relationship with the College of Physicians and Surgeons, the Departments of Nursing Education, and Health and Physical Education of Teachers College. The required clinical practice will be given in the Columbia-Presbyterian Medical Center as well as in outstanding hospitals in the New York area.

Admission requirements for entrance into the nine-month course for physical therapy technicians include two years or sixty semester hours of college work (including courses in physics and biology) or graduation from an accredited school of nursing or an accredited school of physical education.

Admission into the occupational therapy course requires at least one year of college and preferably two. A science, sociology, and psychology are recommended prerequisites. The regular course has been accelerated to approximately two and a half years in length. Candidates already possessing a degree can register on advanced standing and complete the work in twenty-one months or less.

A certificate of proficiency is granted by the University following the satisfactory completion of either of these courses. A limited number of scholarships are available.

Bulletins and further information may be obtained from the Physical and Occupational Therapy Office, Room 312, School of Business, Columbia University.

tral law just the same, and the size of the state has nothing to do with it. If you are a citizen of Delaware or of Texas, you have the same obligation to obey the central law. The local law of the states and the size of states are no obstacles. Forms of government are no obstacle. If you are a subject of His Majesty the King Emperor, or if you are a citizen of the Soviet Union, or of the United States of America, you are equally bound as an individual to obey the Law of Nations. I believe the Russians would be for it; they want peace; after this war they want a law that will say a man cannot do this if it is going to interfere with the peace of the world. You can agree upon this fundamental: that every individual, no matter where he lives, has got to obey the Law of Nations and not do those things which make for war. So I draw to a conclusion and say, we, the people, shall insist upon a Law of Nations, which each one of us will uphold and will obey; otherwise I see the hordes of Genghis Khan sweeping the world, rushing from Asia over Europe; I see the thousands of horsemen of the Huns destroying civilization again; and I see the most terrible of all these calamities, the burying of all that is precious in dust and ashes.

Liberty-loving men, freedom-loving men, watch what is being done. If they are talking in the terms of sanctions by nations against nations, sanctions imposed to maintain world order in the future, if they are talking of pacts and treaties, they are talking in terms of failure. Such methods failed before and will fail again; so let us as the people insist not upon dreams but upon the will to live in peace established by law so that at last mankind may rise to its destiny.

COLD IS LATEST BOON TO MEDICINE

Anesthesia by refrigeration is making possible the development of a new shockless, drugless, almost bloodless surgery, Barclay Moon Newman, Lieutenant, USNR, says in *Hygeia, The Health Magazine.*

"Only a few years ago doctors would have agreed that death was sure to follow if the body temperature went down much below 95 degrees. Today this belief has been exploded," he explains. "More than that—man's ancient enemy, cold, is the chief tool in a number of interesting new technics. One of them is shockless, drugless, almost bloodless surgery. Another is a great boon to shipwrecked seaman. Yet another suggests that human biology can bid time stand still."

In several amputations in which it has been successfully employed as an anesthetic, Lieutenant Newman observes, "the basic reason for the effective help given by ice is very simple: Cold slows down all the processes of life. . . . .

"In any operation, the shock produced by the body's own poisons is one of the chief dangers. When a part of the body is thoroughly chilled, it produces fewer of the poisons that need to be thrown off. Not only are the nerves numbed—which happens when an anesthetic like ether is used—but all the flesh surrounding the nerves is numbed and inhibited as well. Ice surgery not only dulls the nerves that carry the bad news; by slowing down the chemical chain of events it prevents some of the bad news from occurring at all. And as bacteria also are living creatures, cold inhibits their growth and spread through an infected wound. . . .."

About one hundred and fifty years ago experiments were conducted with cold by Dr. James Currie, of Liverpool, England. One of Napoleon's surgeons during the retreat from Moscow noticed that intense cold made amputations almost painless. For the past hundred years or so not much was done in this line, the lieutenant observes, "until 1938, when Dr. Temple Fay and his associates at Temple University, Philadelphia, showed how much more cold the human body can stand than was thought possible. Dr. Fay felt that his attempts to slow the growth of cancer cells by localized icing were promising enough for an experiment in cooling down the whole body. . . . . As far as curing cancer is concerned, this semihibernation, or hypothermia, as physicians prefer to call it, has been a failure. But Dr. Fay took a bold step into the unknown and worked out a technic with which others may find the answer to many stubborn riddles.

'Meanwhile Dr. Frederick M. Allen, of New York, had been following another trail into the unknown. His experimental work had taught him the profound chemical why's and wherefore's of the rule pounded into every first-aider: loosen a tourniquet frequently. In hundreds of laboratory animals he had seen how the release of a tourniquet, if held tight too long, also releases poisons that produce shock and death. He had observed that the degree of shock could be controlled by changing the temperature of the bound limb. The lower the temperature, the lower burned the fires of life's chemistry. Therefore fewer waste products were piling up behind the dam of the tourniquet, demanding to be removed."

The boon of hypothermia to shipwrecked seamen involves its use in the treatment of what is known as "immersion foot," which results from the immersion of a foot in very cold water for long periods of time, as frequently occurs among sailors whose ships have been torpedoed. It has been found that the application of heat in cases of immersion foot results in inflammation, blisters, and intense stabbing pain, with gangrene, amputation, and death sometimes following. It now has been found that the use of cold in the treatment of immersion foot not only reduces or prevents pain but also keeps the danger of gangrene and other complications at a minimum.

Geneticists are intrigued by the possibilities opened up by the discovery that when human male sex cells or spermatozoa are plunged into liquid nitrogen at −319 F. below zero they freeze so quickly that their cell structure is not damaged and when warmed up again a good proportion of them are still alive. Investigators in this field report that the spermatozoa could be kept in this frozen state indefinitely and still remain alive.—*A.M.A. News*

Amendments to Food Rationing Meet New Needs*

RECENT amendments to food rationing orders, involving osteopaths, condensed milk, fats, oils, and hospitals, are summarized in the *Journal of the American Medical Association* for July 17 as follows:

"The Office of Price Administration announced on July 2 that any medical practitioner authorized by the state in which he practices to prescribe all internal drugs is also authorized to certify that a person requires supplementary food rations for health reasons. Authority to make such certification was previously confined to doctors of medicine. OPA has now broadened the authority so that osteopaths in states which license osteopaths to prescribe all internal drugs may also prescribe supplementary food rations. Food rationing regulations provide that a person whose health requires more rationed food than his ration points permit him to buy may apply to his local board for necessary additional points. In some illnesses foods are prescribed in addition to drugs or medicines, or as a substitute for them. In some counties the work of ration boards in processing such applications has been much simplified through the voluntary help of the doctors themselves. By establishing panels to review all medical certifications and to advise the boards, responsibility for issuing extra rations for health reasons has been kept on a professional level.

"The Office of Price Administration under date of June 1 placed evaporated and condensed milk on the list of rationed products. These types of milk are added to the group of rationed foods containing meats and fats, for which red ration stamps are needed, without any increase in the total number of points allowed for this group. One point is required for one 14½ ounce can or for two 6 ounce cans or for two 8 ounce cans. This means that the child may use 7 of his 16 points per week for his milk requirements in terms of evaporated milk, which allows slightly less than the equivalent of a quart of whole milk per day, and have 9 points remaining for his meat and fat requirements. An invalid or any other person whose health requires that he have more canned milk than he can obtain with the stamps in his War Ration Book II may apply at his local War Price and Rationing Board for additional points. The consumer must submit a written statement of a licensed physician showing why he must have more canned milk, the amount needed during the succeeding two months and why unrationed foods cannot be used instead. A supplemental allotment to acquire canned evaporated and condensed milk needed by a hospital to meet the dietary needs of its patients may be obtained on application to its local War Price and Rationing Board. It is understood that, if the present method of rationing does not make evaporated milk available in all areas for infants and children, some more effective method will be worked out.

"The Office of Price Administration has issued an amendment to ration order number 16 (R.O. 16, amendment 25) which permits the use of rationed fats and oils for external therapeutic purposes. This includes the use of vegetable oils, such as cotton seed oil for bathing newborn infants, for external application in skin diseases, for urethral injection or lubrication of urethral instruments, and for x-ray visualization. Such use of rationed fats and oils is defined as "industrial consumption" and persons using these products for such purposes are classified as "industrial consumers." An industrial consumer engaged in the care and treatment of the sick and needing rationed fats and oils for this purpose may apply to his district Office of Price Administration for a certificate with which to acquire them. The procedure to be followed, briefly, is as follows:

The application should be made on form R-1605 to the district office.

If the applicant is a hospital, the district office will pass on the application by using the same method of computing allowances as the local boards use in computing allotments for industrial users; otherwise the application will be forwarded to the Washington office for action. If the applicant requires more than he would receive by the method of computation described, he should also submit form R-315 stating the reasons for such request. An "industrial consumer" to whom a certificate is issued for "industrial consumption" of rationed fats and oils may use it only to acquire the foods for which application was made and may use those foods only for the purpose for which the application was granted.

"For several months the Office of Price Administration and medical authorities have been studying the hospital problem with a view to developing a uniform procedure covering the granting of supplemental allotments for hospitals. Solution of the problem is believed near. In the meantime a provision in the regulations (section 11.6 of general ration order 5) should enable hospitals to obtain the necessary supplemental allotments so that patients need not suffer from dietary deficiency. This provision gives local boards authority to grant such allotments to meet the dietary requirements of patients living in and receiving care in hospitals whether or not such patients are on special diets. In determining the amount of the supplemental allotment of processed foods and the commodities covered by ration order 16, the local board will take into consideration the availability of fresh fruits and vegetables, unrationed substitutions such as poultry and fresh fish, and the physical facilities of hospitals to process and store such foods."

Polio Cases at Highest Since 1934

WHILE accurate predictions are impossible, there is an indication that 1943 may go down on the records as one of the major epidemic years for infantile paralysis. Analysis of the situation at the end of the first twenty-six weeks of the year shows the total number of cases to be higher than it has been for any of the past twelve years, except 1934. During the first six months, 1,084 cases were reported from forty-two states. (The six-month average for the past ten years is 841.)

The most severely affected states are California, Texas, and Oklahoma, with totals of 351, 230, and 33 cases, respectively. In the latter state, however, unofficial reports received since the compilation, for the period ending July 3, indicate that there has been a marked increase.

Medicine and the War

Medical Care for Civilian Defense Workers Injured in Performance of Their Duties

EDWARD M. BERNECKER, M.D.

Commissioner of Hospitals and Chief of the Emergency Medical Service of New York City

BY EXECUTIVE Order of the President of the United States, a plan is now in operation in New York City in cooperation with the United States Public Health Service, through which full compensation is made for medical services rendered by physicians and hospitals to members of the United States Citizens Defense Corps who are injured in the performance of their duties. This includes all members of the five protective services in New York City—namely, the Air Warden Service and the City Patrol Corps of the Police Department, Auxiliary Firemen of the Fire Department, emergency workers in the Department of Public Works and the Welfare Department, and the Emergency Medical Service of the Department of Hospitals. It is the intention of the Public Health Service that payments provided be adequate to furnish, without expense to the patient, his family, or friends, all the medical services and supplies reasonably necessary for proper treatment.

The processing of claims under the War Civilian Security Program by the Federal Security Agency of which the Public Health Service is a branch, requires a number of reports to be submitted on printed or mimeographed forms which are supplied to physicians and hospitals rendering service to civilian defense workers. It would only be confusing to list here the various forms that must be filled out before payment can be approved and authorized by the Chief of the Emergency Medical Service, in whom this responsibility is vested. Therefore, it is suggested that for detailed information regarding payment of claims, physicians and hospitals get in touch with MISS BEATRICE ZEITLIN, *Deputy Personnel Officer*, Emergency Medical Service, Department of Hospitals, 125 Worth Street, New York 13, New York (telephone WOrth 2-4440, Extension 413), immediately upon the application by any civilian defense worker for such treatment.

Scope of Civilian War Medical Care

The general scope and limitations of civilian war medical care are:

(*a*) Subject to the approval of the local Chief of the Emergency Medical Service, medical care may include the services of physicians, dentists, nurses, and attendants, in a hospital and at home; hospitalization at ward rates, nursing or convalescent home care; x-ray and laboratory services; drugs and medical supplies; certain prosthetic appliances; essential transportation; physical and occupational therapy and such other medical services and supplies as may be regarded as necessary by the attending physician.

(*b*) The Public Health Service will furnish only such medical care as may not be furnished under any other such plan (i.e., Federal, State, or local government medical plans, State Workmen's Compensation, Veterans' Administration, etc.).

(*c*) Medical care will not be furnished to any individual otherwise eligible if the Surgeon General determines that his condition resulted from his own willful misconduct.

(*d*) The Chief of the Emergency Medical Service, subject to the limitations set down in carrying out his responsibility, will take whatever steps he considers necessary to ascertain that the treatment instituted is adequate and will arrange for such consultations, special services, or changes in treatment as may, in his opinion, be necessary.

(*e*) Physicians, dentists, and hospitals which have been authorized to furnish services and supplies to the injured worker should submit their itemized bills, prepared in triplicate, made out to the Public Health Service, on the fourteenth day after instituting treatment and at monthly intervals thereafter. The Chief of the Emergency Medical Service will review the services and charges and forward the bills with his recommendations to the War Civilian Security Office in Baltimore, Maryland.

(*f*) Special drugs, prosthetic appliances or other supplies, nursing services, transportation, or hospital care at other than ward rates may be furnished only upon the written order of the attending physician certifying that such services, prosthetic appliances, or other supplies were medically necessary, and with the *written prior approval* of the Chief of the Emergency Medical Service.

(*g*) The determination of the Surgeon General will be final as to services and supplies reasonably necessary for proper treatment or burial, and as to the amounts to be paid in each case for medical care or burial.

(*h*) Payments for all services and supplies will be made at rates not exceeding the minimum prevailing rates in the community for the same services or supplies. Where applicable, rates in common use under workmen's compensation laws, under laws administered by the United States Employees' Compensation Commission and the Veterans' Administration will be used by the Public Health Service as guides in determining the amounts to be paid. Payments for burial will not exceed $100 in any case.

Persons now using their highest skills in war work should not apply for these positions. Appointments in Federal positions are made in accordance with War Manpower policies and employment stabilization plans. Before a definite offer of appointment is made, eligibles are cleared through the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians, of the War Manpower Commission.

Persons rated eligible on the Medical Officer examination of 1941 need not file applications again unless they consider that they now possess qualifications for eligibility in a higher grade or different option.

Further information and application forms may be obtained at first- and second-class post offices, Civil Service Regional Offices, and the Commission in Washington, D.C.

Bacterial Warfare Impractical

IN AN editorial discussing a paper by Col. Leon A. Fox, of the U.S. Army Medical Corps, in which it is pointed out that there are practically insurmountable technical difficulties preventing the utilization of bacterial warfare, the *Journal of the American Medical Association* for July 17 says that "It is hoped that Colonel Fox's paper will be as widely quoted in the popular press as have been the numerous frightening hypotheses that it contradicts." The *Journal* editorial follows:

"The Geneva Disarmament Conference of 1932 considered bacterial warfare serious enough to prohibit its use. This action contributed to the popular fear of pathogenic [disease-causing] micro-organisms as effective military weapons. To allay this fear come two timely reprintings of the classic paper by Col. Leon A. Fox, of the U.S. Army Medical Corps, which summarize the current opinion of military experts.

"Threatened introduction of new weapons or methods of warfare has often had to overcome opposition based on ethical, religious, or humanitarian grounds. The early use of gun powder had to overcome opposition of this type. Military history, however, teaches that a weapon has never been abandoned for such reasons unless displaced by more effective weapons or until adequate countermeasures have been developed. Military history also reveals that epidemics were often the determining factor in past wars. In many campaigns contagious diseases caused such great loss of life and such large numbers of noneffectives on both sides as to lead to a stalemate. In other campaigns great differences in the degree to which the two opposing armies reacted to such epidemics occurred.

"The major military pests of the past have been the enteric [pertaining to the intestines] fevers, typhus, bubonic plague, and smallpox, with influenza, the pneumonias, malaria, measles, meningitis, and syphilis playing a minor role. Popularly, it is often assumed that these diseases would be particularly effective military weapons. However, fully virulent causative agents cannot be prepared in large quantities and cannot be introduced in adequate doses into the bodies of unprotected and nonimmunized enemy populations. The essential problem of bacterial warfare from an offensive point of view is therefore the problem of mass production of military pathogens and of devising safe and effective methods of inoculating the enemy. The whole group of enteric infections, for example, could probably never be successfully used as instruments of warfare. Real epidemics of these diseases are traceable only to infected drinking water. While contamination of reservoirs and municipal storage tanks is militarily feasible, such contamination would be largely ineffective because of routine filtration or chlorination methods. Modern sanitary methods, therefore, should be adequate countermeasures against this type of bacterial warfare.

"Among the respiratory infections, a number of maladies are serious enough to be effective if ways of using them can be devised. The two diseases of this group most frequently mentioned are influenza and meningitis. In neither disease could the infective agent be prepared in sufficient quantities, virulence, or stability for military use. The meningococcus, for example, is so delicate that it rapidly dies when exposed for even a few hours to temperature much below that of the human body. The only feasible methods of introducing meningitis into opposite forces would be by human carriers. This would be hardly worth while, since any military aggregation of great size already has so many meningitis carriers (anywhere from 2 to 30 per cent) that the introduction of a few more carriers would be of little moment.

"The use of insect-borne diseases has also been repeatedly mentioned in the press, bubonic plague being the most frightful example. Possibly airplanes flying low could drop recently infected rats on opponent terrains. Even this, however, would probably not start an epidemic. Plague has been more or less endemic as a rodent disease on our own Pacific Coast for over a generation, yet there have been no local human cases in this region sufficiently numerous to be designated as epidemic. Only 6 cases of plague developed in 1924 among European troops stationed in the Punjab, in spite of the fact that 500,000 cases developed in the indigenous population. Typhus also would be ineffective, since control of typhus is a question of louse control.

"Tetanus, gas gangrene, and anthrax have been suggested as particularly effective military pathogens, since they are caused by resistant, spore forming bacteria capable of prolonged periods of viability [ability to live after birth] without loss of virulence outside the animal body. These microorganisms, however, do not produce epidemics, even though they are of military interest as wound invaders. Effective methods of preventing and treating wound infections have been developed. Since wound invaders are omnipresent in nature, the indiscriminate distribution of a few additional wound invaders would not add appreciably to the present dangers of combat.

"One of the commonest scares concerns the dissemination of 'deadly bacterial toxins,' of which botulinus toxin seems to be the pseudoscientific favorite. True, 'an airplane can carry sufficient (botulinus) toxin to destroy an entire city,' provided a carefully measured lethal dose of this toxin is administered orally, subcutaneously [beneath the skin] or intrarectally [into the rectum] to each inhabitant of that city. The release of food materials, contaminated with tremendous amounts of this toxin might conceivably cause a wholesale local destruction of rodents and sparrows. At most the number of human casualties would be negligible. Bacterial toxins like bacteria are readily destroyed by heat and are therefore inactivated by cooking. They are wholly unsuited for use in shrapnel or other projectiles.

"Bacterial warfare is often extended in popular literature to include the use of boll weevils, corn borers, and other agricultural pests. Most of these

We know from records for the past twenty-five years that the peak of each year's outbreak, when figured for the country as a whole, is not reached until sometime between mid-August and mid-September. These records further reveal that the sharp increase in incidence occurs between July 1 and September 1, with a corresponding sharp decline during the ensuing two months.

Even if 1943 has only an average number of cases, there will be difficult problems for those areas that experience epidemics. With so many doctors, public health workers, nurses, and physical therapy technicians serving in the Armed Forces, most communities won't be as well prepared as in former years to cope with an outbreak. Many will find a real challenge in the problem of providing ordinary and adequate care for their population without the added burden of an epidemic of infantile paralysis.

One of the most difficult phases of providing care for patients in an infantile paralysis outbreak is that of supplying sufficient physical therapists trained in the Kenny method of treatment of this disease. There are less than 2,000 registered physical therapists in the United States. Only a small part of those remaining for civilian practice have had any training in this newer method of treatment of early cases of infantile paralysis. The shift in emphasis in treatment from one of rigid immobilization to one of early physical therapy has created a new demand for the services of physical therapy technicians. That demand cannot be met without careful planning and some sacrifice.

The National Foundation is doing all it can to supply these trained workers to epidemic areas. Technicians are being borrowed from nonepidemic areas and assigned to hospitals where the need is greatest. It must be realized that there are not enough trained technicians to go around if and when epidemics spread and increase beyond a certain point. A physical therapy technician can care for only a limited number of patients—certainly never more than 15 or 20 mild cases—and her full time may be taken up by as few as 6 cases with extensive involvement. Neither nurse nor physician can substitute for the physical therapy technician. To add further to the problem, it is only through special study that the technician can master the details of the early physical therapy of infantile paralysis.

The National Foundation, with the aid of its many chapters, is rendering real service. The need, in epidemic areas, not only for more skilled workers, but also for wool, respirators, and hospital equipment, has been met. Chapter funds have helped to meet the hospital and medical expenses of many patients who otherwise might have been unable to secure the proper care when it was most needed.

It is certain that there will be not only many more cases of infantile paralysis during this present year, but also many more areas with epidemic outbreaks. The difficulties and hardships brought about by these epidemics will be reduced to the very minimum where chapters work and plan with the local and state medical and health authorities.—*National Foundation News*

Examinations for Medical Guard-Attendants and Technical Assistants

THE Civil Service Commission has announced an examination to secure Medical Guard-Attendants and Medical Technical Assistants for the U.S. Public Health Service.

Applicants for *Medical Guard-Attendant* positions, which pay $1,970 (counting overtime compensation) a year, must be registered graduate nurses, or have had at least three years' service in the Medical Corps of the Army or Navy, or have had eighteen months' service as hospital attendant-guards in any one of the Department of Justice penal or correctional institutions; in the Medical Center for Federal Prisoners, Springfield, Missouri; or in the U.S. Public Health Service Hospital at Lexington, Kentucky, or at Fort Worth, Texas.

It is desirable that applicants should have had satisfactory experience as guards in penal or correctional institutions, as soldiers, sailors, or marines, or as hospital or asylum attendants.

Applicants for the *Technical Assistant* positions, which pay $2,433 a year (counting overtime compensation), must possess the qualifications for Medical Guard-Attendant and in addition must have had one year of training or experience in one of the following options: Clinical Laboratory Technic, Pharmacy, or X-ray Laboratory Technic.

Applicants must have reached their twenty-first birthday. There is no maximum age limit. No written test is required. Persons now using their highest skills in war work should not apply. Appointments in Federal positions are made in accordance with War Manpower Commission policies and employment stabilization plans.

Persons who received eligible ratings under the examination announced for these positions in July, 1941, need not apply again.

Further information and application forms may be obtained at first- or second-class post offices, Civil Service Regional Offices, and the Commission in Washington, D.C.

Medical Officers Needed for Federal Civilian War Service

THE critical shortage of physicians to engage in vital war work in the civilian branches of the government continues. The great need for these men resulted in the announcing of a liberalized civil-service examination for Medical Officers in 1941. The Civil Service Commission has just revised and reannounced this examination.

The twenty optional branches under which doctors may apply range from General Practice to Aviation Medicine. Those appointed will perform professional duties as doctors of medicine in active practice in hospitals, in dispensaries, in the field, or in rural areas; or in bureaus of the government, such as the Veterans Administration, Civil Aeronautics Administration, Public Health Service, and Food and Drug Administration. Doctors will also be used in industrial establishments under direction of the War Department.

Applicants for all grades must have received the degree of M.D. from an accredited medical school. Applicants for the Senior Medical Officer grade ($5,228 a year) must have had at least five years of appropriate medical experience; for the Medical Officer grade ($4,428 a year), three years of experience in addition to a required internship; and for the Associate Medical Officer grade ($3,828) one year of internship.

The salaries quoted above include overtime pay.

There are no written tests and no age limits.

veterans and classmates in medical school, more than half a century ago.

"Much as he has enjoyed his profession, Dr. Howland would choose dentistry if he had a chance to make a second start in life.

"'For a dentist's time is his own,' he said. 'Heisn't on call at any hour of day or night as a doctor is.'

"Dr. Howland's affiliations include the Erie County Medical Association, the American Medical Association, the Spanish-American War Veterans' Association, the American Legion, and the Veterans of Foreign Wars."*

Kings County

Contributions amounting to $32,375 have been subscribed toward the $40,000 annual development fund of the Long Island College of Medicine by business organizations, labor unions, doctors, alumni, and residents of Brooklyn, it was announced recently at the third report meeting of vice-chairman and workers held in the office of Dr. Frank L. Babbott, chairman of the college's board of trustees and former president of the college.

At the meeting Dr. Jean A. Curran, president of the school, explained the basis of the new military training program at the college. He said that under the program the government will confine financial aid to the expenses of the men assigned to the college for medical training.

No government funds, he pointed out, can be used to finance extension of the college's program such as the development program will provide.

He added that it is the obligation of the college to maintain the institution at maximum usefulness to the community and to expand its program of education, service, and research as medical development makes it necessary.*

Monroe County

The Nutritional Committee of the county society recently visited the Albion plants and laboratory of Snider Packing Division of General Foods Corporation.

The group, headed by Dr. G. Kirby Collier, included the following Monroe County doctors: Dr. C. B. F. Gibbs, Dr. C. W. Warren, Dr. R. L. Sommers, Dr. John Aikman, Dr. S. W. Clausen, Dr. N. G. Orchard, Dr. John Murlin, Dr. S. S. Bullen, Dr. B. J. Duffy, Dr. William A. Sawyer, Dr. Charles S. Lakeman, Dr. Estelle Hawley, Dr. L. C. Boynton, all of Rochester, and Dr. D. G. Cooper and Dr. Paul H. Mahany, of Albion.

The doctors were the guests of Snider's at a luncheon served at the Town Club.*

Nassau County

Dr. Arthur J. Harrington, of Hempstead, will resume his practice of medicine at his home address on September 1.

Dr. Harrington has been a patient at Mercy Hospital for the past several weeks and is reported as convalescing now.*

New York County

In order that an invasion of parasitic diseases from the tropics may be forestalled, training of medical and laboratory students in insect identification and other branches of parasite study has begun at Columbia University under the direction of Dr. H. Randolph Halsey, lecturer in zoology at the College of Pharmacy.

The establishment of these courses was based on the epidemic of parasite infections in certain sections of the world that lasted almost three years after the last war. Army and Navy officials have recognized the possibility of another insect plague by reason of "increased air travel, aerial combat over the tropics, and the presence of our troops in tropical areas."

• • •

The Physicians' Home was presented with a check in the sum of $240.31 by Dr. J. Stanley Kenney, president of the Medical Society of the County of New York. This check represents the proceeds of a testimonial dinner tendered to Doctor Kenney on May 19, 1943.

As part of the new teaching arrangements entered into between the New York Eye and Ear Infirmary and the College of Physicians and Surgeons of Columbia University, Dr. J. Morrisset Smith has been appointed to the School of Medicine faculty as professor of clinical otolaryngology and executive officer of the department of otolaryngology at the Infirmary. Dr. Conrad Berens is professor of clinical ophthalmology and executive officer of the department of ophthalmology. Instruction will continue to be given at the Infirmary, utilizing the clinics, operative surgery, and other hospital facilities.

• • •

The American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, organized October 17, 1942, was incorporated on May 27, 1943, with the following objects:

1. To create a body of duly qualified physicians who are specialists in otorhinolaryngology and who have training and experience in plastic and reconstructive surgery.
2. To stimulate, to study and research, to investigate and advance in the field of plastic and reconstructive surgery, and to promote the interchange of ideas, of theory, and practice; and to maintain the highest ethical standard of practice.
3. To encourage and forward the investigation, study, and advancement, and to render every possible service to preventive medicine.
4. To encourage and forward the establishment of a school for the training of physicians in the field of plastic surgery.
5. To encourage and forward the establishment of institutes dedicated to the practice of the art of plastic and reconstructive surgery.

The officers elected for the year 1943–1944 are as follows: president, Dr. Romeo Luongo of Philadelphia; vice-president, Dr. Morris Bender; secretary, Dr. Jacob Daley; treasurer, Dr. Nathan Settel, all of New York City.

• • •

Dr. Joseph Lo Presti, Assistant Surgeon, United States Public Health Service Reserve, has been assigned to the National Society for the Prevention of Blindness for work in the field of industrial eye hygiene.

Ervin A. Tusak, M.D., has been promoted to clinical professor of ophthalmology at New York University College of Medicine for the academic year 1943–1944.

Oneida County

Dr. Thomas A. McGoldrick, of New York City, president of the Medical Society of the State of New York, was the guest speaker at the regular meeting

pests, however, take several years to propagate and invade a sufficient terrain to be effective economically. This would violate one of the fundamental laws of military science, since it might merely interfere with postwar economics, reducing the ability of a conquered nation to pay indemnities.

"Summarizing his argument, Colonel Fox concludes that there are 'practically insurmountable technical difficulties preventing the use of biological agents as effective weapons of warfare.' In this h confirms the previous opinion of numerous Germa bacteriologists, who, five years before the first worl war, were assigned the task of suggesting safe an effective weapons of bacterial warfare. Ehrlich, fo example, replied that 'nothing [he] could sugges would be of more than a nuisance value to the enemy and might even be a source of danger to our own troops.'"

County News

Albany County

At the meeting of the county society on June 23, the scientific address was "Chemical and Functional Testing as Aids in the Diagnosis of Some Important Clinical Entities." The speaker was Dr. Maurice Bruger, associate clinical professor of medicine at New York Post-Graduate Medical School, Columbia University, and chief of the Division of Pathological Chemistry, New York Post-Graduate Hospital.

Participating in the discussion which followed were Drs. James F. Rooney, Kenneth E. Crounse, Arthur W. Wright, and John J. Clemmer.

Bronx County

At the June meeting of the county society the following officers were elected: *president*—Frederick W. Williams, 1000 Grand Concourse, Bronx 56; *president-elect*—Moses H. Krakow; *vice-president*—Frank La Gattuta; *secretary*—Goodlatte B. Gilmore, 2940 Grand Concourse, Bronx 58; *treasurer*—Joseph A. Landy, 900 Grand Concourse, Bronx 56.

Cayuga County

Dr. M. LeRoy Seccomb, president of the Cayuga Health Association, has announced the appointment of a committee to represent the Association in cooperating with the Cayuga County Medical Society, the State and City Departments of Health, and employers in a chest x-ray program among industrial workers and migrants.

Dr. George C. Sincerbeaux, of Auburn, is chairman of the committee. Dr. John W. Copeland, chairman of the Public Health Committee of the Cayuga County Medical Society, is a member.

The program will enable employers to give their employees a chest x-ray at a very reasonable cost to the employers and without cost to the employees.

The information revealed by the x-ray will be confidential between the employee and his family physician or the plant physician.

Many plants in Auburn are planning to offer this service to their employees.*

Erie County

Dr. Lopo de Mello, director of the Syphilis Control Service of the Buffalo City Department of Health and Medical Consultant of the Division of Syphilis Control of the New York State Department of Health, has been commissioned in the United States Naval Reserve as a Lieutenant Commander. Dr. I. Jay Brightman is replacing Dr. de Mello in both positions.

• • •

The Buffalo *Courier-Express* recently carried an interesting article about a Buffalo doctor, from which we quote:

"As contract surgeon of the 23d College Training Detachment of the U.S. Army, charged with the medical and surgical care of the 500 aviation students stationed at the University of Buffalo, 78-year-old John D. Howland, M D, is doing his full share toward the winning of the war This is the third war in which Dr. Howland has done his part During the Spanish-American War, he served as a major in Cuba, and in World War I, he was a lieutenant-colonel, commanding 3,600 men He and his regiment took part in the battles of Verdun and Metz.

" 'In both wars, I was a combatant,' Dr. Howland said I declined to serve in the Medical Corps, for, in those earlier years, I was eager for thrills and wanted to risk my life for my country. Today, I have to be satisfied to serve here at home; for, although exceptionally fit for a man of my age I'm not in condition for field service '

"At 78, Dr. Howland drives his car through all sorts of traffic, reads all but the finest print without glasses, hears perfectly, retains a good set of natural teeth, and possesses a head of hair many a man of 50 well may envy. Dr Howland requires only five hours' sleep in twenty-four hours A few weeks ago, he worked twenty-two hours without rest.

"Six years ago, at the age of 72, Dr. Howland retired, two years beyond the usual retirement age, from the post of physician to the Erie County Hospital, which he had filled for twenty-seven years. During the intervening years, he maintained a small private practice and cared for scores of Spanish-American War veterans of this vicinity. But that wasn't enough work to occupy a man of his vigor, ability, and intelligence. To the most casual acquaintance, it's obvious he's glad to be doing an important, time-consuming job again

" 'I look forward to many years of useful living,' Dr. Howland stated. 'My father attained the age of 86 years, and a couple of my aunts had more than 100 birthdays.'

"Born in New Bedford, Connecticut, June 12, 1865, Dr Howland comes of the oldest New England stock His first American ancestor, for whom he is named, was John Howland who came to these shores aboard the good ship Mayflower back in 1620, and was an officer of the guard of the Plymouth Colony.

"Before he was a year old, Dr. Howland came with his family to Buffalo, and has lived here for more than 77 years Before entering medical college, he worked in the transportation industry, having been identified with the Lackawanna New York Central, and Erie railroads and the Lackawanna steamship line. During college vacations, he used to serve as wheelsman on Great Lakes vessels.

"Shortly after his graduation from the University of Buffalo Medical School, in 1891, Dr. Howland visited friends in New York City, through whom he became well acquainted with the late Theodore Roosevelt.

'At the outbreak of the Spanish-American War, Dr Howland left a flourishing practice to serve his country. At the close of that war, he continued as an officer of the 65th regiment, and kept proficient in military matters. After World War I, he maintained his military connections until the retirement age of 64.

"For ten years, Dr. Howland was Erie County medical examiner. Subsequently, he became physician to the Erie County Hospital. When he joined its staff, the hospital's location was the present University of Buffalo campus. In 1926, he moved with the hospital to Millgrove

"Since his wife's death, his daughter, Mrs. Viola Christie, has shared his home They live at 141 Minnesota Avenue, Buffalo. Dr. Howland's son, Howard, is associated with the I. R C

"Dr Howland observes that because of the constant use of the automobile young men joining the armed forces today are less sturdy than his contemporaries of the Spanish-American War.

"Dr. Howland likes people, and gets a great kick out of keeping up his friendship with fellow Spanish-American War

The county society, at its first meeting since the death of Dr. Andrew Sloan, voted a resolution in memorium, as submitted by Dr. F. T. Owens.

The resolution follows:

"In the death of Dr. Andrew Sloan on April 21, 1943, this society lost one of its most devoted and loyal members.

"Practicing in this city for more than forty years, he was, to our knowledge, always a most active and conscientious physician.

"His attitude of constructive interest was recognized by his election and appointment to many important offices: president of our county society; first vice-president of the Medical Society of the State of New York; Oneida County delegate to the state society for many years; delegate to the American Medical Association; medical director of St. Luke's Hospital; one of the founders and, for ten years, president of the Utica Academy of Medicine; president of the Utica Medical Club; and a fellow of the American College of Physicians.

"His extensive practice made for him countless friends, to whom, as to us, his death brings a very personal loss.

"Therefore, Mr. President, we, the undersigned committee, move that this society adopt these resolutions offered in respect to the memory of Dr. Sloan and that a copy of these resolutions be entered upon the permanent records of the society of the County of Oneida and that they be published in the daily press and a copy sent to Mrs. Sloan as a respectful expression of our deepest sympathy."*

Hospital News

Parnall to Direct Investigation of Mental Hospitals

ARCHIE O. DAWSON, chairman of the special Moreland Act Commission appointed last May 26 by Governor Thomas E. Dewey to investigate New York State's mental institutions, announced on July 16 that Dr. Christopher Gregg Parnall, medical director of the Rochester General Hospital, Rochester, since 1924, has been named to direct the investigation.

Mr. Dawson said that the five-man commission selected Dr. Parnall from more than a dozen candidates and his name was sent to Governor Dewey for approval. The Governor, he said, prevailed upon the Rochester hospital to give its director a six-month leave for the survey. Mr. Dawson said the commission hoped to have a report ready for the Governor in time for the convening of the Legislature next January 1.

Mr. Dawson said Dr. Frederick C. MacCurdy, newly appointed State Commissioner of Mental Hygiene, has already made improvements in the department and has promised help in the study. Dr. MacCurdy replaced Dr. William J. Tiffany as commissoner when Dr. Tiffany retired during the original investigation of Creedmoor State Hospital in Queens Village. Dr. George W. Mills, superintendent at Creedmoor, also resigned and his place is temporarily filled by his assistant, Dr. Jesse L. Bennett.

Dr. Parnall, a former president of the American Hospital Association, went to Rochester General Hospital in 1924 after serving six years as professor of administrative medicine at the University of Michigan, where he received his medical degree in 1904. While there, he was director of the university hospital, including the State Psychopathic Hospital.

Dr. Parnall will have offices for himself and a staff on the ninth floor at 61 Broadway. Mr. Dawson said he did not expect any public hearings until fall.

With Mr. Dawson on the commission are Dr. Peter Irving, of New York City, secretary and general manager of the Medical Society of the State of New York; Dr. Fraser D. Mooney, of Kenmore; Charles Roswell, of Springfield, Queens; and Assemblyman Lee B. Mailler, of Cornwall. Its counsel is Alfred J. Bohlinger, of New York City.—*New York Herald Tribune, July 17*

Many Apply for Service in Hospital Units

ACCORDING to recent figures, more than 1,000 physicians and dentists have applied for association with the Affiliated Hospital Units for civilian defense, which were recently organized under the aegis of the Office of Civilian Defense and the U.S. Public Health Service.

Members of the staffs of affiliated units are commissioned in the inactive reserve of the U.S. Public Health Service, generally with ranks equivalent to those of captain, major, or lieutenant colonel in the Army. They remain on inactive status except when there is an emergency arising from an air raid or other grave wartime disaster. When called to active duty, they then receive the pay and allowances of officers of equivalent grade in the armed forces. They are expected to furnish service only in their own or neighboring states, and their obligation ceases at the termination of the present national emergency. The nature of the service is recognized by authorization to wear a lapel button which indicates that they have enlisted for emergency service. They do not wear a uniform until called to active duty and need not purchase one unless directed to do so when called to active duty.

The Board of Trustees of the American Medical Association and the Directing Board of the Procurement and Assignment Service have authorized essential physicians to accept positions with these affiliated units.

Some physicians have expressed the fear that acceptance of these commissions might involve them in a responsibility to the U.S. Public Health Service and might in some way encourage the acceptance by the profession of the proposed Wagner-Murray-Dingell bill. This is a misunderstanding. Those who become associated with affiliated units are under no obligation to serve in any other capacity, no matter what functions Congress may someday see fit to thrust on the U.S. Public Health Service. Duties of members of affiliated units are limited strictly to those which they have agreed to assume as a result of enemy action.

Improvements

A Sarlar suction and ether machine now being used at the Batavia Hospital is of the latest design and made of the best material. The hospital's old machine is being repaired and parts are being renewed so that it can serve as an auxiliary machine for bedside use.

The new machine is the gift of the Batavia Hospital Woman's Auxiliary.

The ether vaporizer part of the machine pumps ether vapor to the patient either in a mouth tip or a tracheal catheter, the amount of ether being controlled by the anesthesist as he judges the patient's needs to maintain the depth of anesthesia necessary while the surgeon does his work.

The big advantage of this is that the ether can be given continuously, even though the patient's mouth or face must be covered or worked upon. A unique feature of this machine is its portability, which makes it available for use in supplying air pressure when needed.*

FIRST WOMAN ARMY SURGEON

In a July issue of the *New York Times Magazine*, Bessie Phillips brought into public light again the story of the Army's first woman doctor.

It is all the more interesting to New Yorkers because Dr. Mary Walker was a native of New York State, the daughter of a doctor in Oswego. Following the profession of her father, she graduated from the Syracuse Medical College at the age of 23 and began practice immediately in Columbus, Ohio. Six years later she returned to her home town.

Perhaps in those days, too, there was some opposition to accepting a woman doctor for military service, for Dr. Walker volunteered her service and entered the Union Army as a nurse, serving in that capacity for three years before she was commissioned a first lieutenant. Then as assistant surgeon, she held that rank until her retirement in June, 1865.

According to the records, Dr. Walker was as skilled as her male contemporaries in amputating legs and arms, suturing incisions and alleviating suffering. She dressed in the blue uniform like her brother officers, with a gold stripe running down the trouser legs, an officer's overcoat, and a black felt hat with gold cord, similar to the G.A.R. hat. Her jacket was cut like a blouse and fitted loosely at the neck.

Her adoption of male attire was a part of her general and lifelong struggle for women's rights and dress reform. After the war she continued to wear male attire—a frock coat, long trousers, a low beaver hat, and men's shoes. She also pioneered in the short hair-do for women, wearing her hair about as long as a man's when he is in need of a haircut.

Her proudest possession was a bronze medal, with an inscription on the reverse side reading, "Presented by the Congress of the United States to Mary E. Walker, A.A. Surgeon, U.S. Army." No record of the occasion of the conferring of this honor was made by the War Department and it was deleted from the list by the Board of Records in 1917. But shortly after the Civil War it was reported that Dr. Walker had been awarded the "Congressional Medal of Honor and Bravery" for services on the battlefield.

An army pension supplemented her income from private practice and lectures which she carried on almost to the end. She died at the age of 87 in 1919 at her home, Brinker Hill, near Oswego, as a result of a fall on the Capitol steps in Washington two years previously.

[Continued from page 1554]

The maternity division recently completed and furnished in the new annex of Ilion Hospital is now open for inspection by the public, Miss Hazel Buckley, superintendent of the maternity division, has announced.

The nursery was the gift of Dr. B. J. Kelly, of Frankfort, and is regarded as the most completely equipped in the vicinity. It contains 16 cribs and a heated dressing table that insures an even warmth for babies, their bath, and clothing.

Adjoining the nursery is a kitchen for the preparation of formulas, with separate refrigerator. The new wing also contains a waiting room and a solarium.

The old maternity division is being converted for general hospital use and renovations are in progress to connect that section with the new hospital building.

The new annex, one of the most modern in this area, is not scheduled for official opening until fall, but the maternity division has been fully completed and may be inspected by anyone interested, Miss Buckley says.*

Faced, like hundreds of other hospitals, with the urgent necessity of housing new nurses and other personnel for whom room is not available in regular quarters, Methodist Hospital, of Dallas, Texas, found the answer in "Victory Housing." The completely prefabricated, portable, and demountable, small houses are cool in summer and readily kept warm in winter because of the air-space insulated and ventilated double roof.

As many as 10 to a freight car or 5 to a convoy truck, depending on the type, can be rushed to hospitals where housing is critical. Five hundred "Victory Homes" a day can be produced by the Dallas plants, which have made tens of thousands that are used by the armed forces. They are manufactured in multi-units or in single units.

• • •

An immediate campaign for a wartime "Victory Fund" of at least $75,000 for the Eastern Long Island Hospital at Greenport was undertaken by unanimous resolution of the Board of Directors at a special meeting.

The main purpose of the fund is to provide for construction of an additional building adjoining the new structure built in 1939. A secondary purpose is to meet the annual maintenance deficit which the hospital incurs in treating most of its patients at less than the cost of their care.

The new building is to be known as the "Victory Wing" of the hospital and will be dedicated to the memory of North Fork residents whose lives are lost in World War II.

Construction is to begin as soon as materials are available at advantageous prices and in a place where the work will help to stabilize employment.*

At the Helm

Leighton M. Arrowsmith, administrator for the last fourteen years of St. John's Hospital, Brooklyn, heads the new hospital unit of the institutional user branch, food rationing division of the OPA, it was announced by Archie Palmer, associate director of the food rationing division.

An All-American football end who forsook a promising career on the professional gridiron to study medicine has been placed in charge of the Urologic service at Rhoads General Hospital in Utica.

It was back in the 20's that George Tully, now Captain Tully, won gridiron prominence with the Dartmouth Indians, then coached by Jesse Hawley. In 1925, the year sportswriters were acclaiming Hawley's team as the mythical national champions, Tully was named All-American end on the Associated Press and United Press teams.

After his graduation from Dartmouth, Captain Tully played two seasons with the Philadelphia Yellowjackets, a professional gridiron team. He took up the study of medicine in the University of Vermont College of Medicine, receiving his M.D. degree in 1931.

He interned in Worcester, Massachusetts, his home city, then took a residency in urology at Morrisania City Hospital, New York City.

Upon completing his residency, Captain Tully opened an office for the practice of his specialty in Worcester in 1934. In 1938, he was appointed instructor in urology at the University of Vermont College of Medicine, a post which he retained until he was called into active service last November. Prior to his assignment to Rhoads in May, Captain Tully was stationed at Lovell General Hospital, Fort Devens, Massachusetts.*

A VITAMIN CITY

City officials of Howey-in-the-Hills, Florida, are considering seriously changing the name of the place to "Vitamin City."

A scientific check of hundreds of Northerners, suffering from sinus troubles and common colds, who have spent short periods of time at this Floridian resort has revealed that such visitors have benefited considerably as a result of the visit. Credit is largely given to the consumption of large quantities of citrus fruit juices and inhaling the citrus fruit scented air, as well as to absorbing the Florida sunshine.

Howey-in-the-Hills, in addition to its natural scenic beauty, is noted as the location of the world's largest citrus fruit groves. It has long maintained a policy of giving visitors all the freshly-squeezed orange or grape fruit juices, made from tree-ripened fruit, that they can consume. The vitamin drinks are as free as water.

In their research, they claim to have also found that adolescents with acne have been relieved of this embarrasing condition through drinking ample daily quantities of freshly-squeezed grape fruit juice. In some instances the skin has cleared completely after a very short time; and in every case some improvement has been rapidly attained.

Howey-in-the-Hills is just 25 miles northwest of Orlando in the central part of Florida, and is located on Lake Harris, one of Florida's largest inland waters.

THE SHAPE OF TOMORROW

In *"The Spirit of Enterprise,"* recently published book by Edgar M. Queeny, some possiblities of the future suggest the limitless horizons of industry now that it has generally embraced science.

Mr. Queeny writes, "The day may come when workers will travel a hundred miles from country homes to offices and factories by helicopter bus.

"There will be prefabricated houses warmed by heat from tiny wires buried in the walls. Rooms will be air-conditioned for summer comfort, illuminated by cool, germicidal light, and equipped with built-in, low-temperature refrigeration. There will be new fruits and vegetables—larger, without seeds. Radios will be static-free and television in full color will be commonplace.

"Clothes will be made of extruded fabric and stockings will be molded and waterproof, stainproof, flameproof and as easily cleaned as a pair of rubber boots."

pathologist at the hospital. Dr. Peckham has been in ill health for some time.

In his long career at Vassar hospital, Dr. Peckham has been responsible for many changes in the laboratory. When he was appointed director of the laboratory in 1918 at the request of the late Guilford Dudley, then president of the board of trustees, there was only one laboratory assistant. Today the staff consists of 5 full-time technicians. He has also given a great deal of his time and valuable knowledge to the advancement of young scientific careers by allowing college and medical students to work in the laboratory.

A native of Schenectady, Dr. Peckham graduated from Union college in 1896 and received his medical degree from Hahnemann Medical college in Philadelphia.

Upon completion of his medical education Dr. Peckham went directly to Poughkeepsie and started practice, with offices in his home. When he became pathologist at Vassar Hospital, he gave up his private practice and devoted all of his time to the laboratory.

Dr. Peckham is director of the Dutchess County Health Association and has served as secretary of the association since its inauguration. He is also a director of Vassar Brothers Institute.

Dr. Taylor, who will begin his new duties at Vassar Hospital about September 1, is a native of Danbury, North Carolina.

He attended the University of North Carolina and was graduated from John Hopkins Medical School, where he also served his internship and acted as resident in pathology for three years.

In 1932 he became associate director of the Ayre Clinical Laboratory in Philadelphia and since May, 1934, he has been in charge of the Kingston City Laboratory.

Dr. Taylor is president of the New York State Association of Public Health Laboratories and president of the Ulster County Medical Society.

He is also a member of the Pathological Society of the State of New York; the Philadelphia Pathological society; and the Physiological Society of Philadelphia.

His wife, Dr. M. Elizabeth Moore, plans to continue her practice in Kingston for the duration of the war.*

Work in occupational therapy at Kings County Hospital was highly praised in an article by Ruth G. Davis published in the Brooklyn *Eagle* of July 18. We quote:

"Trained therapists and trained volunteers are a crying need today, for there are not enough to meet the demands of the Army nor the civilian hospitals. Brooklyn can boast of only one occupational therapy department in a general hospital, the one in Kings County Hospital. What a fine example of occupational therapy it is!

"Occupational therapy, often referred to as a 'work cure,' is remedial treatment in the form of supervised activity for persons injured in body or mind by accident or disease. There are four such occupational therapy shops at Kings County, under the direction of Miss Anna M. McNulty. Occupational therapy is a development of the 'keep them busy' idea to therapeutic treatment and is now given under directions from physicians and surgeons.

"In 1918 Kings County developed a new department to create diversion for the chronic patients of the Home for the Aged and Infirm. A small portable building heated by a coal stove was the headquarters, and only men were permitted to work. Miss McNulty directed the work, which at the time consisted of the making of brooms, brushes, window shades, etc. Miss McNulty, who recently has observed her twenty-fifth anniversary at Kings County Hospital, now has a staff consisting of 5 trained occupational therapists—Miss Dorothy Sniffen, Miss Florence Stattel, Miss Helen Peck, Miss Louise Craven, and Miss Orvilla Yost. These young women are kept busy in the four O.T. shops at

ELECTRONIC "EYE" MEASURES SUNFALL

Sensitive new electronic "eyes" to see and record invisible ultraviolet rays in sunshine will soon begin their first daily measurements of "sunfall" in the United States to study its effect on the wartime health of the nation.

The new sun-measuring instruments eventually will operate in twenty of the world's first solar observation posts to be set up for a nation-wide ultraviolet study by the United States Weather Bureau. Located in Weather Bureau stations, the observation posts will be scattered over a 1,000-mile stretch of land running from Texas northward through the Mississippi Valley to the colder regions of the Middle West.

The first sun metering will get under way soon in New York City and in Boston and Cambridge, Massachusetts, to record the amount of ultraviolet which penetrates through the haze of big metropolitan centers. These figures may eventually make it possible to forecast for several days in advance the intensity of sunfall over a city, Weather Bureau officials believe—*Med. Times*

WEEK A YEAR PER EMPLOYEE LOST

Illness accounted for the loss of five and one-half days of working time per year per employee in a typical cross section of American industry studied by experts of the Industrial Hygiene Foundation, collaborating with the U.S. Public Health Service.

These studies, which concerned illness not due to industrial accidents, were announced through the annual report of the Mellon Institute of Industrial Research.

When only absences of eight days or longer due to illness were considered for the 1941 period in 14 companies the annual per employee loss was two and one-half days. Eight per cent of the men and 10.5 per cent of the women employed suffered these illnesses. When absences of one day or longer were considered, estimates showed that 50 per cent of the men and 82 per cent of the women took time off because of illness.

In one company the sickness absenteeism loss amounted to $180 per employee annually when reduced efficiency before and after illness was estimated and included.—*Science News Letter*

in whooping cough

Elixir Bromaurate

GIVES EXCELLENT RESULTS

Cuts short the period of the illness and relieves the distressing spasmodic cough. Also valuable in other Persistent Coughs and in Bronchitis and Bronchial Asthma. In four-ounce original bottles. A teaspoonful every 3 to 4 hrs.

GOLD PHARMACAL CO. NEW YORK CITY

[Continued from page 1558]

Kings County, which comprise the inpatient shop, where those able to walk or be wheeled can get their exercise; the wards, where movable apparatus is brought to the patient's bed; the outpatient shop where a released patient may return to continue treatment; and a diversion shop for orthopaedic conditions. There was at one time an occupational therapist for the neurological department, but for lack of help it has been temporarily closed.

"The rugs woven by the patients, the coat hangers, magazine racks, and other objects made by the patients are sold by the department to maintain their shops, as they receive no financial help aside from the original equipment and the payment of salaries by the city. All the crates for lemons, oranges, and other supplies discarded by the hospital dietary department are utilized by the staff.

"During the development of this beneficent treatment over the past twenty-five years, the Brooklyn committee of the New York City Visiting Committee has given occupational therapy its support and encouragement through its hospital occupational committee."*

* * *

Lt.-Comdr. Mildred A. McAfee recently inspected the newly-built barracks for the Waves who are stationed at the National Naval Medical Center in Bethesda, Maryland.

Now there are 200 officers and enlisted women scattered throughout the four commands at the center—hospital, research, dental, and medical. The jobs they do are varied and important.

Lieutenant (j.g.) Mildred Mitchell, a psychologist, with degrees from Rockford University, Radcliffe College, and Yale University, is with the neuropsychiatric service at the hospital. In all of the Navy there are only thirty psychologists doing hospital work. The twenty-nine others are men.

Ensign Sonya Lemish, of Rome, New York, a pretty girl with red-gold hair, a graduate of Smith College, was with the Rockefeller Institute for Medical Research before she joined the Navy. At Bethesda she is working on secret experiments with blood plasma.

Because research chemists cannot be made in a day, all of the girls in this department had experience before they joined. Pharmacist's Mate Second Class Minnie Davis had been for five years a laboratory technician with the Tulane Medical School and the Jackson, Mississippi, Public Health Department before she joined the Navy.

Waves are assigned to the hospital corps at their own request, provided they have had some training for this work or show an aptitude for it. Those without technical training start out as corpsmen and are taught all types of hospital work. When on ward duty they learn how to keep charts, administer medicines, make beds, serve food, take care of equipment, and generally help nurses, doctors, and patients. They are also assigned to laboratories, clinics, and offices, where they learn to keep records, operate x-ray machines, take blood tests, etc.

Some of these "hospital apprentices," as they are called, continue with this work. Others who have had some previous experience, or have specialized during their corpsman study, become pharmacists' mates, such as dental assistants or technicians in the medical laboratory. Lieutenant (j.g.) Margaret May Diehm, head of the laboratory and the senior officer at Bethesda, explained that the girls in her department are rotated from job to job so that they can broaden their knowledge while doing the actual daily work that must be done. This "learn while you work" method is in use throughout the hospital.

Before the Waves arrived, there was no occupational therapy department at Bethesda. It was started when Ensign Jane Cassidy, a graduate of Mills College and the Philadelphia School of Occupational Therapy, was sent there. Working closely with her is Ensign Barbara Stephens, a graduate physiotherapist, who studied in London and had been working, before she joined the Waves, with the Rhode Island Infantile Paralysis Foundation—*New York Herald Tribune*

HEPVISC IN HYPERTENSION

LOWERS HIGH BLOOD PRESSURE

Relieves Hypertensive Symptoms • Prolongs Hypotensive Action

Each tablet contains a synergistic combination of 20 mg. Viscum album, 60 mg. desiccated hepatic substance and 60 mg. desiccated insulin-free pancreatic substance.

Dosage 1-2 tablets t.i.d. Sample on request

Available in bottles of 50, 500 and 1,000 tablets.

"SPARE THE DOCTOR" DRIVE OPENED

"First Aid to Doctors" is the theme of a recent publicity campaign among the residents of Monmouth County, New Jersey, and sponsored by the Red Bank and Long Branch Leagues of Women Voters.

Using newspaper articles and four-minute speakers, the leagues hope to acquaint the residents with their own serious shortage of physicians and show them how they can do their part.

Before the war, Monmouth County had 159 doctors in active practice. Now, for one reason or another, there are only 98. Although the government Public Health Service considers that one doctor for every 1,500 persons is the minimum for safety, this county has only one doctor for every 2,000 persons.

To spare the doctor, the leagues suggest that the patient "see him at his office as soon as you feel under the weather; don't wait until you are seriously ill. Don't ask for sympathy calls or for extra attention. Be cheerful and patient while you wait for him."

"Study and practice the rules of good nutrition," the leagues urge. "Get plenty of rest and fresh air. Take the Red Cross course in home nursing . . . . and the Red Cross course in first aid; proper attention to small injuries may prevent serious results. Do not ask for a private-duty nurse unless your doctor urges it."

BRIGHAM HALL HOSPITAL
AT CANANDAIGUA, N. Y.
FOR MENTAL AND NERVOUS PATIENTS. An uninstitutional atmosphere. Treatment modern, scientific, individual. Moderate rates. Licensed by dept. of Mental Hygiene. REVIEWED

Diseases of the Breast. By Charles F. Geschickter, M.D. Octavo of 829 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1943. Cloth, $10.

This is an encyclopedic treatise on diseases of the breast, both benign and malignant, with 593 illustrations. While there is a full description of classification and pathology of all types of tumors, the reader may be prompted to turn to the 300 pages devoted to malignant diseases and their treatment. There is an agreement with the conclusions of Adair that radical mastectomy is the treatment preferred, with preoperative radiation only in those cases in which there is a question of operability and postoperative radiation when it is found that the disease is not well within the limits of dissection. The final chapter is on the experimental production of benign and malignant tumors. Dr. Geschickter has produced an important contribution to the study of breast diseases, whether or not one agrees with his classifications or is willing to follow his dictum in treatment.

JOSEPH RAPHAEL

Aftereffects of Brain Injuries in War: Their Evaluation and Treatment. By Kurt Goldstein, M.D. Octavo of 244 pages. New York, Grune & Stratton, 1942. Cloth, $4.00.

The author of this book has had a rich experience in brain injuries that occurred in German soldiers during the first World War. He had the opportunity of following many of these patients for approximately ten years after the war. The result of such an experience is now available in book form.

There is a chapter devoted to symptomatology, another one to neurologic symptoms, and one to mental symptoms. Other chapters are devoted to the origin of symptoms and the psychologic laboratory examinations in which many tests are described in detail. The treatment is described in a chapter devoted to physical and neurologic therapy and in a separate chapter on social adjustment.

The book is a valuable contribution to the management of brain injuries and is a very opportune one in view of the large number of cases that are inevitable in the present war. It is highly recommended to all who are interested in the subject.

IRVING J. SANDS

The International Medical Annual: A Year Book of Treatment and Practitioner's Index. Editors: H. Letheby Tidy, M.D., and A. Rendle Short, M.D. Sixtieth year, 1942. Octavo of 396 pages, illustrated. Baltimore, Williams & Wilkins Co., 1942. Cloth, $6.00.

This popular yearbook is published for the sixtieth year in spite of many harassing circumstances. It is to the credit of the editors that, in spite of the bombing of their publishing works, they have suc-

MILTON PLOTZ

Endoscopic Prostatic Surgery. By Roger W. Barnes, M.D. Octavo of 232 pages, illustrated. St. Louis, C. V. Mosby Co., 1943. Cloth, $6.00.

This thorough yet concise monograph was designed by the author as a text to which urologic house surgeons or other urologists could refer while learning the technic of endoscopic prostatic surgery under the supervision of an experienced operator.

With the aid of many clear illustrations, the author emphasizes such points as the anatomy of the all-important true and surgical capsules and of the prostatic blood supply.

Foremost among the indications for endoscopic prostate surgery is the training to resect accurately and quickly enough to keep the operating time to about one hour. If his series of transuretheral resections is comparatively limited, the operator should restrict utilization of this technic to the smaller glands until he has gradually worked up to the larger ones.

The author uses the Stern-McCarthy electrotome routinely but the Nesbit and Gibson one-hand modifications with the use of the free hand for rectal manipulation of the prostate are described.

With respect to the actual technic of resection, the strict necessity for keeping the loop within the area of the prostatic urethra is emphasized. The importance of the verummontanum as the guardian landmark of the external sphincter is also made clear.

In summary, the author describes endoscopic prostatic surgery as a comparatively safe, rapid, and almost painless means of alleviation, with shorter hospitalization time and end results that compare favorably with those of other methods of prostatectomy.

FEDOR L. SENGER

Creatine and Creatinine Metabolism. By Howard H. Beard, Ph.D. Octavo of 376 pages, illustrated. Brooklyn, N. Y., Chemical Publishing Co., Inc., 1943. Cloth, $4.00.

The author has reviewed all experimental and theoretic work on creatine and creatinine metabolism since 1926. He has added much new material and has correlated the chemistry and tests for creatine and its relation to clinical medicine.

The most important part of the book, from the reviewer's point of view, is its description of general muscle metabolism, the synthesis of creatine, and its conjugation from the simple amino acids by methylation. There is a chapter on creatine in relation to water metabolism and also one on creatine content in heart diseases.

The book is well written and should be in the library of anyone who is interested in biochemistry and metabolism.

MORRIS ANT

The Hospital Care of the Surgical Patient. By George Crile, Jr., M.D., and Franklin L. Shively, Jr., M.D. Octavo of 184 pages, illustrated. Springfield, Ill., Charles C Thomas, 1943. Cloth, $2.50.

This is a well-prepared handbook which describes the procedures used in caring for surgical patients in the Cleveland Clinic. One section, which is of considerable importance, is devoted to physiologic principles as related to surgery. Another section is devoted to the prevention management of surgical complications. A third part describes in detail most of the common hospital procedures.

The book will naturally be of great use to the surgical intern and also to the older surgeon who has neglected to keep abreast of the newer developments.

EDWARD P. DUNN

Diseases of the Skin. By Oliver S. Ormsby, M.D., and Hamilton Montgomery, M.D. Sixth edition. Octavo of 1,360 pages, illustrated. Philadelphia, Lea & Febiger, 1943. Cloth, $14.

This book in its previous editions has always set a very high standard and this edition is carrying on the tradition of the past. The book has been thoroughly revised and the subject-matter brought up to date. The references are complete and cover the literature well. Even rare dermatoses which are frequently not covered in the ordinary dermatologic text are adequately covered in this work. The illustrations are excellent and adequate to bring out the details mentioned in the text.

Altogether, this edition should be found in the library of all dermatologists who desire a complete reference work.

JOHN C. GRAHAM

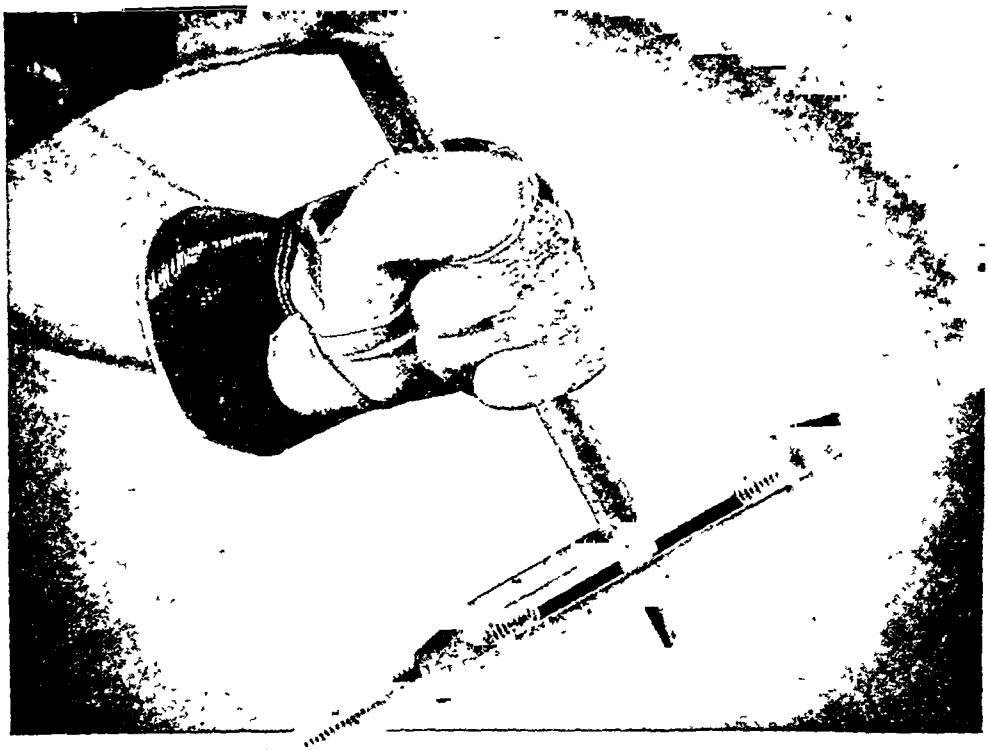
Physiological Psychology. By S. R. Hathaway. Octavo of 335 pages, illustrated. New York, D. Appleton-Century Co., 1942. Cloth, $2.75.

The book offers nothing new from the standpoint of physiology of the nervous system. However, since it is intended to orientate students of psychology primarily in the physiology of the nervous system, it is presented in a simplified fashion to meet their knowledge and needs.

The material is comprehensive and up-to-date.

Aside from chapters on emotions, sleep, and intelligence, there is very little of psychology included in the book.

JOSEPH L. ABRAMSON



Burns, Shock, Wound Healing and Vascular Injuries. [Military Surgical Manuals, Vol. V.] Prepared under the Auspices of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. Octavo of 272 pages, illustrated. Philadelphia, W. B. Saunders Co., 1943. Cloth, $2.50.

A concise manual prepared by various specialists in the field of surgery for medical officers of the armed services.

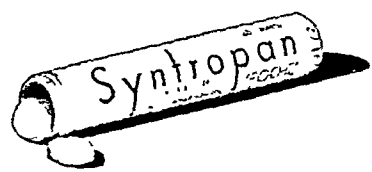
As indicated by the title, the book is divided into four sections. The material is well organized and outlined for rapid review of diagnosis and treatment. Both sides of controversial matters are discussed. Five chapters on burns comprise the largest section of the volume, with references to relevant articles at the end of each chapter. The sections on "Burns" and "Vascular Injuries" are both profusely illustrated. The chapters on "Shock" and "Wound Healing" present the latest thoughts on these subjects.

This work should prove to be of invaluable aid to those who are preparing to meet the surgical emergencies of today.

RALPH WOLFE

Tension Relaxed

Syntropan,* the Roche non-narcotic antispasmodic, effectively relaxes the tension of smooth muscle spasm.



INDICATIONS: Syntropan 'Roche' is indicated in pylorospasm, cardiospasm, intestinal colic, spastic constipation, gastric spasm, peptic ulcer, megacolon, and tenesmus.

DOSAGE: One tablet (50 mg) three or four times a day, or as required. By subcutaneous or intramuscular injection, one ampul three times a day, or as required. HOFFMANN-LA ROCHE, INC., ROCHE PARK, NUTLEY, N. J.

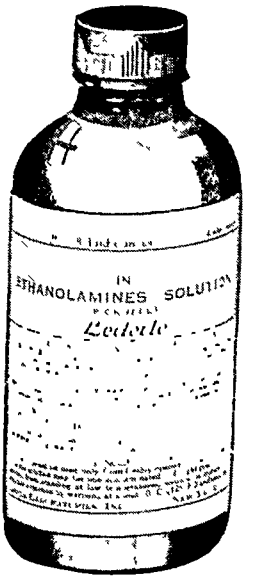
The local and constitutional bacteriostatic treatment of burns with . . .

SULFADIAZINE



Lederle

BACTERIOSTATIS is essential for healing in extensively burned areas. This may be achieved by appropriate surgical and medical measures adopted immediately after the injury is received. The most important bacteriostatic measure is the use of sulfonamides.

SULFADIAZINE *Lederle* may be employed locally in the form of "SULFADIAZINE IN ETHANOLAMINES SOLUTION (PICKRELL)" *Lederle*, or "SULFADIAZINE OINTMENT" *Lederle*.

SULFADIAZINE *Lederle* may be given by mouth if drug blood levels remain insufficient to inhibit bacterial growth Caution should be observed in the simultaneous use of oral and local therapy since excessive drug blood levels may result. Maintenance of urinary output between 1,000 and 1,500 cc. daily and an alkaline urine are advisable during intensive Sulfadiazine therapy.

PACKAGES

Sulfadiazine in Ethanolamines Solution (Pickrell) *Lederle*
Available in bottles of 8 oz. and 1 pt.

Sulfadiazine Ointment 5% *Lederle*

Decholin
REG U S PAT OFF
COUNCIL ACCEPTED FOR TWELVE YEARS

THE ORIGINAL DEHYDROCHOLIC ACID

Decholin — chemically pure dehydrocholic acid — initiated a new era in bile salt therapy. Prior to 1929, therapy was restricted to desiccated bile products, mixtures of variable composition and of uncertain therapeutic action.

Decholin prompted an imposing chain of research studies on the physiology and pathology of the gallbladder, bile ducts, and the liver. Of the 408 original research investigations on the clinical value of dehydrocholic acid, all are based on Decholin.

Decholin is the most potent hydrocholeretic available. It increases elaboration of bile as much as 200 per cent, affording a valuable means of flushing the biliary passages. The toxicity of Decholin is lower than that of any other known bile acid, so low that its sodium salt, Decholin sodium, is given intravenously. Decholin is contraindicated in complete obstruction of the hepatic or common bile duct.

Epinephrine Hydrochloride 1:1000 N.N.R.

CHEPLIN'S solution of this powerful vasoconstrictor, hemostatic and circulatory stimulant is adjusted to a definite standard strength and is physiologically assayed by measuring the effect on blood pressure.

EPINEPHRINE HYDROCHLORIDE may be administered by hypodermic, inhalation or topical application, affording rapid relief of asthmatic symptoms, urticaria, angioneurotic edema, reactions following injections of biologicals, shock or collapse, and prompt control of certain types of hemorrhage. When used in conjunction with topical, nerve block or infiltration anesthesias, it produces a bloodless operative field and retards absorption of the anesthetic—thus prolonging the period of anesthesia. Literature on Request.

EPINEPHRINE HYDROCHLORIDE is packaged as 1:1000 in:

1 cc. ampules.
10 cc. rubber-stoppered vials.
30 cc. rubber-stoppered vials.
30 & 480 cc. bottles for topical applications.

"PRE-TEST"
VAGINAL INFECTIONS

In many cases you can clear up a vaginal condition with a single prescription of STA-O-GEN Vag-I-Caps.* In any case, a box of 12 is ample for a 2-week "pre-test" period, to determine the severity of the infection. As you know, STA-O-GEN'S prolonged, continuous liberation of nascent oxygen is harmless yet powerfully germicidal, fungicidal and deodorizing. The symptomatic effects annoying your patient are relieved immediately — odor is eliminated—discharge reduced and irritation soothed. If, after this "pre-test" therapy, trouble persists, you can be certain the case will warrant the time and effort required for a comprehensive diagnosis; while your examination and treatment will be less of an ordeal. *Ozonide of Olive Oil in 45 minim soluble gelatin capsules. David Nye Barrows, N. Y. State Jr. Med. Vol. 41, Jan. 15, 1941.

STA-O-GEN Liquid for office and Vag-I-Caps for home use are available through any wholesaler or direct from

Something can be done

Under adequate ERTRON therapy, the arthritic patient can be rendered free from pain; mobility can be increased considerably; and the systemic evidence of metabolic disturbance can be controlled.

In the hundreds of cases studied intensively in leading arthritis clinics, the improvement in *Ertronized* patients followed quite closely a definite pattern:

First, a generally improved sense of well-being—increase in appetite and strength; better mental outlook. In undernourished patients, a gain in weight usually follows. This earliest evidence of favorable response indicates the systemic action of ERTRON. Passive mobility is next improved and, lastly, pain is gradually reduced, allowing greater active mobility.

. for the Arthritic . . . .

Ertronize the Arthritic Patient

The mass of accumulated evidence demonstrating the value and safety of *Ertronization* therapy, based on years of experience with this proved form of treatment, justifies its use as the treatment of choice as soon as the diagnosis of chronic arthritis is confirmed.

ERTRON—the only high potency, electrically activated, vaporized ergosterol (Whittier Process), is made only in the distinctive two-color gelatin capsule.

Supplied in bottles of 100 and 50 capsules.

ALSO NEW 500 CAPSULE BOTTLE

ERTRON is promoted only through the medical profession.

PRIODAX

TABLETS

for dependable cholecystograms

Accurate gallbladder diagnosis is now more certain with PRIODAX, a new contrast medium which owes its superiority to its form and composition.

Iodine, (51.5%) firmly bound, in a stable organic molecule produces reliable, clear pictures of uniform density by the "single-dose" method.

Contains no phenolphthalein or any related derivatives. thus reducing the possibility of diarrhea with loss of contrast material.

Tablet Administration and chemical nature favor retention. Vomiting ...so often associated with unpalatable powders...is *rare* with PRIODAX.

Administration · Six tablets swallowed whole in the course of a light fat-free evening meal. X-ray exposures are made in 12 and 15 hours.

PRIODAX, β-(4-hydroxy-3, 5-diiodophenyl)-α-phenyl-propionic acid, supplied in cellophane envelopes, each containing six tablets. Boxes of 1, 5 and 25 envelopes.

NCING-

THERAPEUTIC AGENTS

Neo-Synephrine Sulfathiazolate

combines powerful vasoconstriction and potent bacteriostasis in one stable chemical compound

In response to widespread demand, Stearns research has linked into one stable chemical compound the vasoconstrictive properties of Neo-Synephrine and the bacteriostatic action of sulfathiazole.

The worth of this new product can be judged from the fact that the therapeutic value of both agents is undiminished.

Neo-Synephrine Sulfathiazolate provides the same fast, sustained decongestion of engorged mucous membrane as Neo-Synephrine, with the same relative freedom from undesirable side effects—combined with the bacteriostatic potency of sodium sulfathiazole.

Convenient to use and safe to administer, Neo-Synephrine Sulfathiazolate provides the medical profession with a powerful new tool for the alleviation of symptoms of colds and sinusitis.

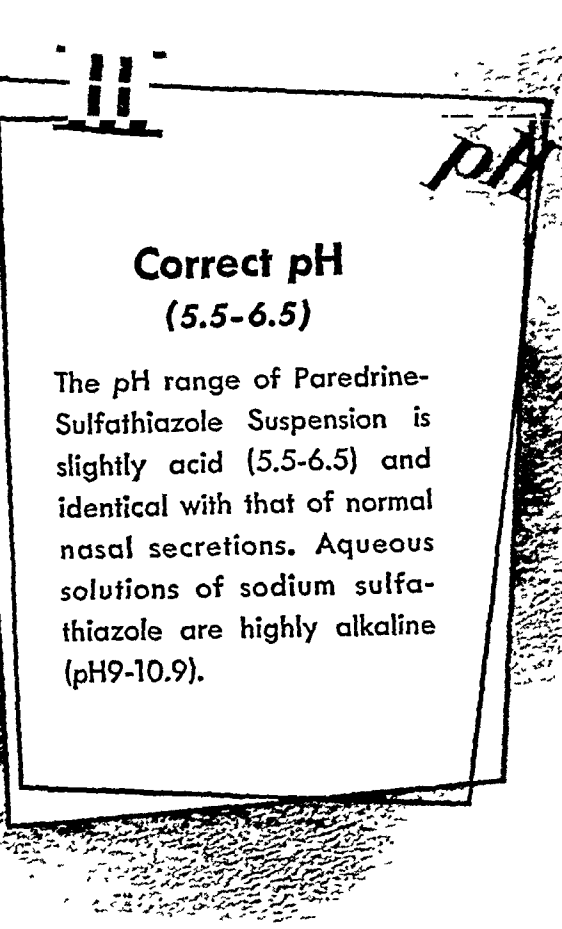
THESODAN
Brewer
The ORIGINAL ENTERIC-COATED TABLET OF THEOBROMINE SODIUM ACETATE

EFFECTIVE
in Coronary Artery Disease and Edema*



Clinical experience and carefully controlled studies in *humans* have definitely proven the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal diseases, and the value of the enteric coating in permitting adequate dosage without causing gastric distress.

Supplied—in 7½ grains with and without Phenobarbital ½ grain; in 5 grains with Potassium Iodide 2 grains and Phenobarbital ¼ grain (cost approximately $1.50 per bottle of 100 tablets); and in 3¾ grains with and without Phenobarbital ¼ grain (cost approximately $1.00 per bottle of 100). Capsules, not enteric coated, are available in the same potencies for supplementary medication.

*Literature giving confirming bibliography, and physicians samples will be furnished on request

SULFATHIAZOLE SUSPENSION

Advance in Intranasal Sulfonamide Therapy

Correct pH
(5.5-6.5)

The pH range of Paredrine-Sulfathiazole Suspension is slightly acid (5.5-6.5) and identical with that of normal nasal secretions. Aqueous solutions of sodium sulfathiazole are highly alkaline (pH9-10.9).

Paredrine-Sulfathiazole Suspension is strikingly effective, both with adults and children, in the treatment of nasal and sinus infections—particularly those secondary to the common cold. Furthermore, it may often prevent dangerous sequelae, such as pulmonary flare-up, otitis media, pharyngitis, laryngitis, etc.

When a vasoconstrictor alone is indicated—

Remember

PAREDRINE HYDROBROMIDE AQUEOUS

THE NEAREST APPROACH TO THE IDEAL VASOCONSTRICTOR

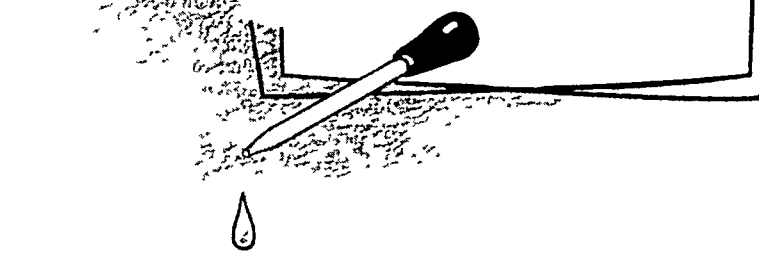
REASONS WHY

PAREDRIN

is a Revolutiona

'Micraform' Sulfathiazole

'Micraform'* crystals of sulfathiazole—approximately 1/1000 the mass of ordinary commercial crystals—make possible a smooth, magma-like suspension, which ensures:—



(1) Uniform deposition and "frosting" over infected areas.

(2) Enhanced and prolonged therapeutic effect.

*Trademark

Effective Vasoconstriction

'Paredrine'—the nearest approach to the ideal vasoconstrictor—possesses a shrinking action more rapid, complete and prolonged than that of ephedrine in equal concentration, without stinging, irritation, ciliary inhibition, or undesirable side effects.

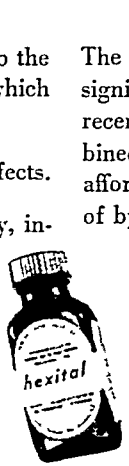
SMITH, KLINE & FRENCH LABORATORIES • PHILADELPHIA

ORTHO presents:

hexital

(HEXESTROL PHENOBARBITAL)

A Step Forward in Menopausal Therapy



In presenting Hexital, Ortho makes available to the medical profession a new therapeutic agent, which affords three distinct advantages:

Lower incidence of nausea and other by-effects.

More complete control of symptomatology, including alleviation of nervous disturbances.

Convenience for the patient, in that two frequently-prescribed medicaments may be obtained in a single prescription.

The estrogenic component of Hexital, hexestrol, is significantly less toxic than stilbestrol. Moreover recent clinical investigations indicate that the combined use of hexestrol and phenobarbital (Hexital) affords an even further reduction in the incidence of by-effects.

Hexital is supplied in scored tablets for oral use. Each tablet contains 3 milligrams hexestrol and 20 milligrams phenobarbital.

Literature available on request.

CLINICAL VALUE OF MUSCLE EXTRACT

Carnacton *in*

ANGINA PECTORIS ARTERIOSCLEROSIS
OBLITERATIVE ARTERIAL DISEASES

Carnacton is a biologically tested extract of *diaphragm muscle*—a powerful, markedly vascularized muscle with a high metabolic rate—most effective for its purpose. Carnacton is not only a vasodilator but also promotes cardiovascular tone and vigor.

In 1 cc. and 2 cc. ampuls—boxes of 12 and 50; vials of 30 cc. for oral use. *Send for professional brochure.*

CAVENDISH PHARMACEUTICAL CORP., 25 West Broadway, New York

A Valuable Advance

IN ANTACID THERAPY

Magmasil

Free from Astringent Influence
Unburdened by Constipation

An Outstanding

Pharmaco-Chemical

Achievement

•

Magnesium Trisilicate

In a True Magma

•

Contains No

Aluminum Hydroxide

•

Not Constipating

Constipation, the greatest drawback to aluminum hydroxide treatment, need not be feared with Magmasil. In therapeutic dosage Magmasil exerts no influence upon normal intestinal motility.

In peptic ulcer, gastritis, hyperchlorhydria, Magmasil presents a definite advancement in antacid therapy. A magma of hydrated magnesium trisilicate in extremely high dispersion, Magmasil neutralizes 86 cc. of N/10 HCl per teaspoonful (Toepfer's reagent), and exerts this action over fully four hours.

Hence fewer doses are needed, pain is promptly stopped, and does not recur. Night pain is usually prevented by the customary 11:00 p.m. dose, permitting of adequate rest.

The silica (SiO_2) formed upon reaction with the gastric HCl juice affords a valuable protective influence which—together with the acid neutralizing action—assures rapid healing and remission.

Physicians are invited to send for samples and a complimentary copy of the brochure "Twenty Years of Progress in Ulcer Therapy."

THOS. LEEMING & CO., INC.
155 E. 44th St. New York, N. Y.

Magmasil is available through all pharmacies in 12 oz. bottles.

BELBARB

AN *Excellent*

SEDATIVE and HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch f exp P & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 9 minims of tincture of belladonna

Belbarb No. 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

SAFETY UNDER FOOT

No figures are available on the number of injuries due to improper shoes, partly because many of the injuries sustained from falls due to this cause are never treated by physicians and many that are receive little publicity.

Few doctors, if any, have never treated wrenched and sprained ankles, torn ligaments and fractures that have partly if not entirely been caused by badly constructed or ill-fitted shoes. As in all safety work, prevention is preferred in eliminating such hazards.

One step to prevention is the prescription of more suitable footwear and proper fitting. Pediforme service may be the logical prescription in most cases.

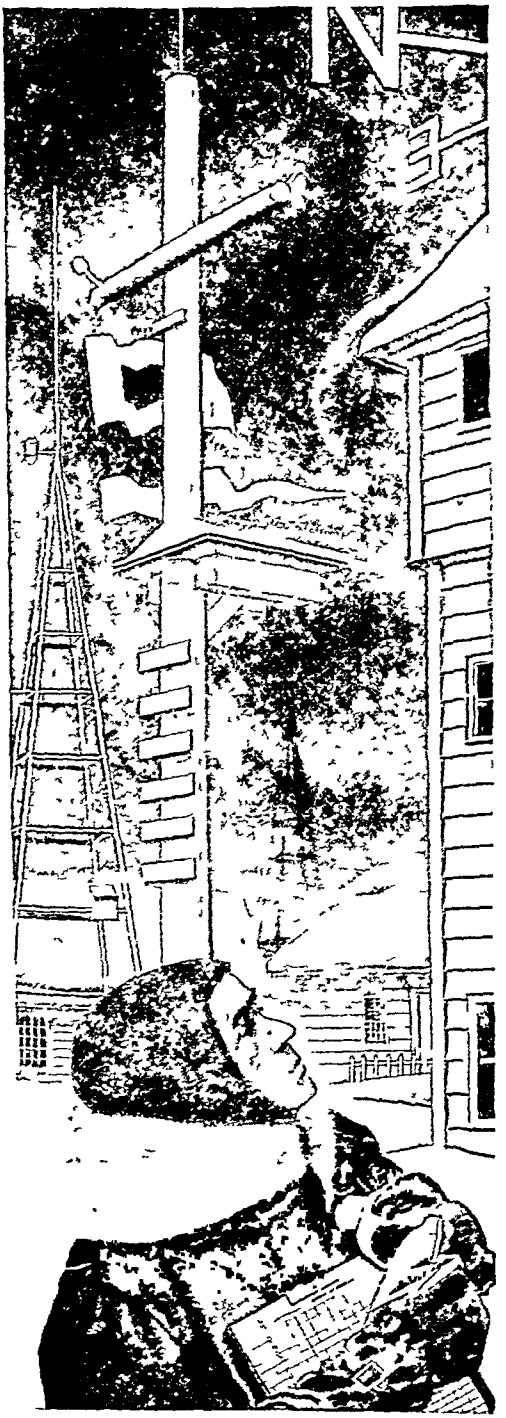
STARTING THE SCHOOL YEAR FORTIFIED

Refreshed by a long vacation period—plenty of health-building sun, fresh air, exercise—children are going back to their classrooms fortified to withstand the rigors of late Fall and Winter.

So that there will be no let-down in their general health and resistance, maintenance of a thoroughly adequate daily diet is important.

Such a diet should include basic food elements plus the important "protective" factors and it is, therefore, suggested should include a daily intake of one pint or more of

HORLICK'S FORTIFIED



Horlick's is delicious whether prepared with milk *or with water.*

Also ideal for between-meals' feeding—Horlick's Tablets—available in conveniently carried (25¢) oval flasks.

Recommend

HORLICK'S

WATCHMAN, WHAT OF THE WINTER?

• In temperate zones, laymen and meteorologists alike know that winter brings foul weather and a tremendous increase in colds and similar disorders of the upper respiratory tract.

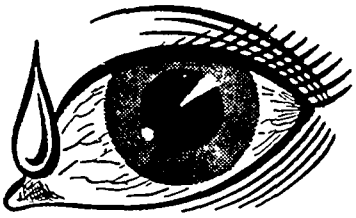
Moreover, if last year's record[1] may be regarded as characteristic, the weekly incidence of colds this winter will rise from a July minimum of about 6,500,000 to around 21,000,000 in mid-February.

As the number of colds increases, working efficiency declines. It has been estimated that one half of all work-time lost in war industries as a result of illness is lost because of the common cold. Thus, during a single four-week period in mid winter, colds accounted for the loss of approximately 1,600,000 man-days of work in war industries alone.

Fortunately, the incidence and severity of colds may be considerably reduced by oral administration of antigens derived from bacteria believed responsible for the severity of the symptoms and duration of the disease. *'Vacagen' Oral Cold Vaccine Tablets* are exceptionally effective. Each provides the water-soluble, antigenic derivatives of approximately 60,000 million organisms of ten different types associated with infections of the upper respiratory tract.

Pneumococcus* (*Diplococcus pneumoniae*)	25,000 million
Streptococcus**	15,000 million
Influenza bacillus (*Hemophilus influenzae*)	5,000 million
M catarrhalis (*Neisseria catarrhalis*)	5,000 million
Friedlander bacillus (*Klebsiella pneumoniae*)	5 000 million
Staphylococcus (*aureus*)	5,000 million

*Types 1, 2 and 3
**Hemolytic, non-hemolytic and viridans



The fresh antigens, extracted from *living* bacteria, are rapidly frozen, dehydrated under high vacuum, and made into *enteric-coated* tablets for oral administration

'Vacagen' Oral Cold Vaccine Tablets are supplied in bottles of 20, 100, 500 and 1,000. Sharp & Dohme, Philadelphia, Pa.

ORAL COLD VACCINE

1 Gallup, G , American Institute of Public Opinion Survey, February, 1943.

HAY FEVER RELIEF

Estivin

ONE DROP IN EACH EYE

The average sufferer from hay fever is chiefly concerned with the elimination of the annoying ocular and nasal irritation.

Relief can be obtained in a simple, convenient and effective manner . . . the routine use of Estivin.

One drop of Estivin in each eye, two or three times daily is generally sufficient to keep the average patient comfortable during the entire season. In more severe cases, additional applications whenever the symptoms recur will keep such patients relieved throughout the day.

POINTS IN FAVOR OF SORPARIN

(Ext. Sorbus aucuparia "McNeil")

IN GALLBLADDER DISEASE

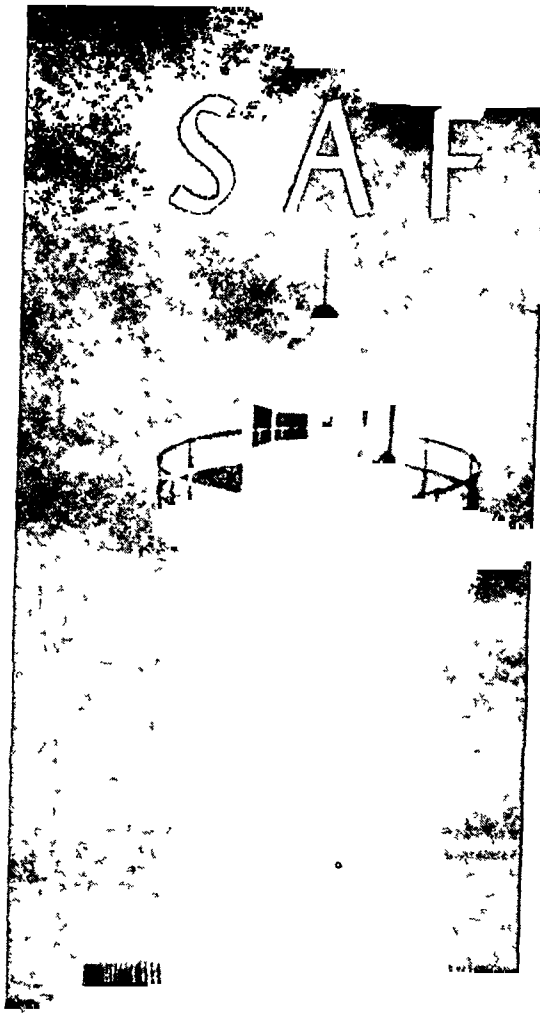
(1) Sorparin is absorbed and utilized in the absence of intestinal bile, and is therefore of value in obstructive jaundice.

(2) Sorparin may be used safely in association with hydrochloric acid, sedatives and antispasmodics without interfering with their action and without any suppression of its own action.

(3) Sorparin has no cathartic action.

(4) Sorparin will elevate the plasma prothrombin within 24 hours, except in the presence of excessive hepatocellular damage.

(5) Sorparin will dispel the dyspepsia associated with biliary tract diseases in 70% or more of the cases both pre- and post-operatively.*



Sorparin is available in tablet form. Each tablet contains Ext. Sorbus aucuparia "McNeil" three grains.

Supplied in bottles of 100, 500 and 1000

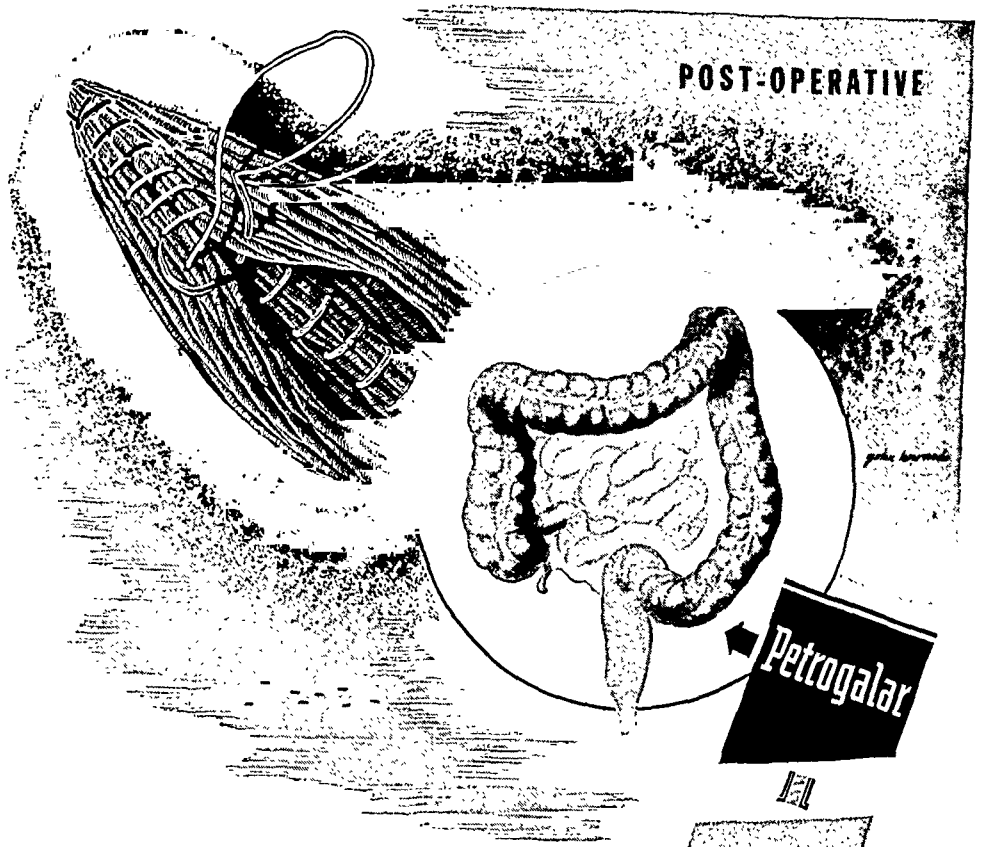
Editorial

Armed Forces Must Have 6,000 More Physicians by January 1*

The armed forces must have 6,000 additional physicians by January 1, 1944, the *Journal of the American Medical Association* reports in an editorial in its August 7 issue. The *Journal* says:



"At a conference of the Directing Board of the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians, held on July 31, with the War Participation Committee of the American Medical Association and in the presence of Mr. Paul V. McNutt, chairman of the War Manpower Commission, and representatives of the Army and Navy medical departments and the Public Health Service, it became apparent that the medical profession must produce toward the winning of the war an additional six thousand physicians for the armed forces before January 1, 1944. Pursuant to a realization of this objective a directive has gone to the generals in command of the various service commands authorizing them to induct into the service physicians between the ages of 38 and 45 who have been declared available by the Directing Board of the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians and who are otherwise subject to Selective Service.

"The needs of the armed forces are real. The members of the War Participation Committee raised with the representatives of the various governmental agencies all the questions that have from time to time challenged the need; the challenge seems to have been met effectively. Indeed, the intimation was made clear that the needs of the armed forces will be met by specific regulations of the Selective Service Administration or the enactment of necessary legislation if required. All physicians up to 45 years of age who have been indicated as available have therefore placed on them now the responsibility for an immediate decision as to their enlistment with the armed forces. The need is so positive that questions of essentiality of men in positions of teaching and research and in industrial medicine are likely to be rigidly reviewed in the near future with a view to extracting from civilian life every one that can be spared.

"As the war continues and intensifies, new needs for the services of the medical profession become apparent. An army in motion and one engaged in the kind of aggressive combat that now concerns our armed forces needs physicians in even greater numbers than have heretofore been demanded. Many thousands of interned aliens and prisoners are now the burden of the United States and must be given medical care.

"If there is any physician who still hesitates under these circumstances, he should realize the added advantage to him of accepting now the commission that is proffered. Should it become necessary in the near future, as seems quite likely, to enlist new activity by the Selective Service Administration and the Officers' Procurement Service to bring in the six thousand physi-

is the antibodies in the blood. All these and other factors play their essential role in the achievement of immunity.[1] It is of more than passing interest that antitoxic immunity does not necessarily follow the recovery from an attack of clinical tetanus.[2] Since all these factors, and perhaps others, play essential roles in the attainment of immunity, we cannot assume that complete immunity is predicated upon a given level of antitoxin in the blood.

Recent military experiences with tetanus in the British Army lend support to this immunologic thesis.[3] In the British Army the practice has been to inoculate the soldiers with two doses of 1 cc. of tetanus toxoid at six-week intervals. Only recently has a boosting dose been given six months later, a vital step in the proper elevation of the level of tetanus antitoxin in the blood.[4] Though the tetanus bacillus is not indigenous to the soil of the Near East, nevertheless clinical tetanus has occurred in men presumably actively immunized, with resulting fatalities. Analyses of these failures would seem to indicate that they were due for the most part to the breakdown of the local factor, for large masses of necrotic tissue played the role of culture medium instead of preventing invasion. A minor role may have been played in some instances by an insufficient level of blood antitoxin due to the lack of a boosting dose shortly before the battle was joined.

The implications of such experiences are plain. The delusion must not be harbored that toxoid injections mean semi-permanent immunity at all events. A boosting dose should be administered shortly before the soldier enters the battle line. Careful and complete surgical removal of all dead tissue should be performed at the earliest possible moment. If this is impossible of achievement, tetanus antitoxin may be indicated in spite of the presence of active immunity, which is normally sufficient but is insufficient in the wake of excessive proliferation of tetanus bacilli in large areas of necrotic tissue. By such precautions the already greatly lowered incidence of tetanus may be further reduced to the vanishing point.

Correspondence

MEDICAL CENTRE
WHITE PLAINS, NEW YORK
August 6, 1943

The Editor
NEW YORK STATE JOURNAL OF MEDICINE

Dear Sir:

This letter is prompted by an editorial in the March 27, 1943, issue of the *J.A.M.A.*, and subsequent notes, especially "Current Comment" in the July 11, 1943, issue: "The Facts on Procurement of Physicians from New York State." These "facts" are just another example of how statistics devoid of explanation may not provide the full story and may even give the false impression that physicians in New York State by-and-large are unwilling to serve in the armed forces of the United States.

If this were an article for publication, it might be entitled either "How the Army Can Procure Additional Physicians" or "Why Procurement Quotas of Metropolitan Areas Are Not Filled."

First, let me make a statement, which I cannot support with appropriate figures but which I believe to be correct, namely: that probably no other single profession has volunteered or is serving so freely in the armed services as the medical profession. A large proportion of these men could have obtained draft exemption and many are beyond the Selective Service age limit, but they all have volunteered at more or less personal sacrifice. There are still many more such physicians willing and ready to serve; some are under 38 years of age and some over.

Probably the greatest deterrent to physicians from the metropolitan areas joining the Army is the economic factor. Most of these men are married and have family and business obligations. They may own homes and offices, not fully paid for; they may have notes due at banks or bills for equipment against which regular payments must be made; and most of them have large insurance premiums to pay. In other words, they have a fixed overhead which must be met, month by month and year by year. What seems to be lost sight of is the fact that this fixed overhead is much higher in metropolitan areas than in the smaller, isolated cities and towns. Many doctors would be perfectly willing to go into the Army if their Army pay would cover fixed overhead, plus enough for their families to live on. The pay of a lieutenant or captain will not do this, as a rule.

What is the solution of the problem? The solution is for the Army to give its medical officers a "break." The cry now seems to be that few additional majors can be appointed from civilian life, because there are so many captains in the service awaiting promotion. There would be room for many hundreds and probably thousands of new lieutenant colonels and majors if medical officers were handled the same as line officers. For instance, according to peace-strength tables of organization, regimental surgeons and battalion commanders of infantry regiments hold the rank of major; however, according to the latest word I

cians that are so certainly required, those recruited by that technic will inevitably begin their service with the minimum commission that is offered—namely, that of first lieutenant. Until that technic is installed, the men of special competence and of years beyond those of the recent graduate have the assurance of careful consideration and a commission more nearly in accord with age and experience.

"The call here made has the approval of the Directing Board of the Procureme and Assignment Service and of the War Pa ticipation Committee of the Americ Medical Association. The medical pr fession may well be proud of the fact that has been the only group given, by directiv of the President, the responsibility of mai taining service in civilian life and at the sam time supplying the needs of the arme forces. Let us not fail in meeting fully th trust that has been placed upon us."

Red-Cell Transfusions

The extensive and universal employment of blood plasma leaves unused the residual red cells. It is almost shocking that in these days when we are so conscious of values that such a useful by-product should have been discarded. In anemia, a prevalent disease condition calling for the addition of erythrocytes, it is noteworthy that the needed red cells, residual from the separated plasma have not been widely utilized.

Red cells were first used for transfusion purposes by the British during the first World War.[1] It may be that the second World War supplied the necessary impetus to the same subject, for several reports have recently appeared advocating the use of red cell suspensions instead of whole blood for transfusion purposes.[2,3,4] In this country this natural use of an invaluable by-product is only lately coming into medical practice.[5] The time has come for us to learn the technic of red-cell transfusion, which has been carefully and fully developed.

Blood from two donors is usually given at a single transfusion. The cells are matched against the recipient's serum to guard against untoward iso-agglutinin reactions. The erythrocytes are then suspended in a physiologic saline solution. Needless to say, the most rigid precautions are taken to insure sterility. To obtain maximal survival it is advisable to employ red cells which have been withdrawn within three days previous to the transfusion. In such suspensions no hemolysis results after the addition of the saline solution. It has been shown that the survival time of erythrocytes in stored blood decreases rapidly after a storage period of more than seven days.[6] English workers have used red-cell suspensions in a concentrated form.[2,3,4] This is advantageous in cases of cardiac insufficiency and other conditions with increased plasma volume. Concentrated suspensions permit the transfusion of large amounts of cells over a short period of time. Sufficient saline solution, however, must be added to prevent undue viscosity of the blood, thus facilitating the flow of blood during the transfusion. A solution of a 100 cc. or 150 cc. of saline added to the cells of 500 cc. of blood has been commonly employed.

The employment of red-cell suspension instead of whole blood for transfusions is a genuine measure of economy. Great quantities of red cells formerly discarded after the plasma was removed from blood now constitute a valuable and easily available by-product. The widespread use of red-cell suspensions will serve to lower costs because of the allocation of expenses between the plasma and red cells. Opportunities are now afforded for more liberal use of transfusions in cases of anemia by the frequent employment of red-cell suspensions.

Limitations of Tetanus Toxoid

The demonstration of an effective titer of antitoxin after inoculation with antigen or toxoid is not a certain guarantee of immunity. Several factors are concerned in the determination of effective resistance.[1] There is the local factor which may successfully repel the invader at the source. Also actively engaged in this combat against the invading organism are the cellular and tissue elements. Another agent, but far from the only factor in the battle for immunity,

Symposium on Plasma

THE PHYSIOLOGY OF SHOCK AND OF BLOOD SUBSTITUTES

H. NECHELES, M.D., Ph.D., Chicago

SINCE 1920, twelve different definitions of shock have been advanced by leading workers in the field. These definitions vary from such extremes as "a decrease in the effective circulating volume of blood plasma," "circulatory deficiency, neither cardiac or vasomotor in origin," "a progressive vasoconstrictive oligemic anoxia," a "state of depression of all the reflexes accompanied by circulatory depression," "the collapse of the circulation from overstimulation of the sympathetic nervous system," to, finally, a "condition of suddenly developing general damage."[1] From the number and wide divergence of these definitions it can be seen that, as yet, there is no complete agreement as to what shock is.

Recently, the work of Knisely and his coworkers[2] on capillaries has established the fact that one of the first signs of damage and developing traumatic shock in the animal is a stickiness and clumping up of red blood cells in the circulation. This process was observed to occur immediately after the diffusion of substances (thrombokinetic) into those capillaries of the traumatized area, through which blood was flowing. By the action of these substances, a sticky film, surrounding the red cells, was produced. All the red blood cells of the animal thus were changed by flowing through the traumatized area. In this way increased viscosity and slowed circulation may be initiated. One of the effects of the use of compression bandages on traumatized areas may be to prevent this phenomenon and, perhaps, thus to prevent shock.

This work seems promising and deserves systematic investigation because the morphologic changes in the blood seen by Knisely and his associates may mean a primary injury to the cardiovascular system, which may initiate the picture of shock.

Most authors agree that in shock a diminution of circulating plasma volume and changes in the peripheral capillary resistance occur.[3] The pallor of the skin and of the peritoneal surfaces in hemorrhagic shock has been noted early by both clinicians and experimentalists.[3] Cannon[4] has expressed the view that vascular changes occurring in shock serve a homeostatic purpose, redistributing the blood in order to maintain the functions of vital organs; vasoconstriction in certain areas may be an adaption of the vascular and vasomotor system to a diminished volume of circulating blood. Gesell[5] has shown that with a loss of only 10 per cent of the total blood volume, the blood flow through the submaxillary gland decreased more than 60 per cent. This occurred even though blood pressure actually had risen. Rein and Roessler[6] showed that with a loss of blood of 2 per cent of the body weight blood flow through the intestines, the femoral artery, and the inferior vena cava decreased 70, 62, and 15 per cent, respectively. Ten minutes later, with blood pressure back to near the control level, the blood flow through the femoral artery was 30 per cent above its control value, while the blood flow through the intestines was 20 per cent below the control level. Blalock and Levy,[7] Freeman *et al.*,[8] and others[1,3] have reported similar results. The former two groups believed that the occurrence of vasoconstriction in shock and, with it, an increase in peripheral resistance were most marked in the organs or tissues which, at the moment, were least active.

In shock, vasoconstriction and increased peripheral resistance on the one hand and capillary stasis and congestion on the other hand have been described by different authors.[1,3] Recently, Wiggers, in a critical review of the literature[3] and in his own systematic work on the hemodynamics of shock,[9] has provided added evidence that the peripheral resistance may actually be decreased in severe hemorrhagic shock.

It is felt that in a consideration of the mechanics of shock the implications of changes in total peripheral resistance may be misleading. Granted that there may be selective vasoconstriction in one or more areas of the body, this vasoconstriction, if sufficiently prolonged, would lead to such anoxia and accumulation of end products of metabolism that abnormal capillary permeability could be expected in such areas.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943. Part of a Symposium on Plasma.

From the Samuel Deutsch Serum Center and from the Department of Gastro-Intestinal Research of Michael Reese Hospital, Chicago.

This work was done under the auspices of the Committee on Research in Shock of the Michael Reese Hospital and was supported by the Michael Reese Research Foundation and by the Nelson Morris Fund.

have, war-strength battalions are commanded by lieutenant colonels, while the regimental surgeon remains a major, despite a tremendous increase in responsibility. It does seem as though the rank of the regimental surgeon could be raised to lieutenant colonel and that of the assistant regimental surgeon to major. Such a change in the tables of organization should not be too difficult to effect. At the same time the ranks applicable to many other assignments possibly could be raised. This would make available a greater number of commissions in the higher grades and thus make it possible for many doctors, who now cannot afford to do so, to enter the Army. I predict that someday the armed forces are going to need many of the group of physicians between the ages of 38 and 45 years. These men are willing to make sacrifices, but they should not be expected to make sacrifices out of all proportion to those of their brethren in other fields of endeavor who remain safely at home enjoying "business as usual."

The Army's policy of confining commissions from civilian life in the higher grades to specialists certified by one of the specialty boards also is open to question. One often wonders if the policy followed in World War I of appointing practically all medical officers in the basic grade of first lieutenant *was not fairer—not that I recommend this policy*, except for its downright fairness and freedom from partiality. As we all know, not all competent specialists are board diplomates; nor are all diplomates or fellows *necessarily* specialists, since many of the latter carry on a general practice. Many physicians conduct a limited practice, without need of becoming "certified," and are as competent specialists as diplomates in their own respective fields—they simply have found no need for becoming "certified." Then, there are many "old-timers" who are excellent general practitioners. These non-certified specialists and general practitioners do not look too kindly on the World War II policy of commissioning only specialty board diplomates in grades above that of captain, and accordingly refrain from applying for or accepting commissions in the lower grades.

There is another group of physicians available and willing to serve in the Army. These are men (several in my acquaintance are under 40 years of age) who are perfectly able to carry on a heavy private practice and yet have been rejected by the Army because of a minor "physical disability." It is my observation that a man with his faculties intact who can stand up under the strain of private practice these days certainly is fit for general hospital or station hospital duty. A more liberal waiver policy would expedite the procurement of medical officers.

Last but not least, physicians should not be forced literally to fight their way into the Army. After all, the "brass hats" are not doing the doctor any great favor in permitting him to give up his practice to go have his head shot off. Treating applicants with courtesy and consideration will help maintain the doctor's interest, as will prompt and expeditious handling of inquiries, physical examinations, and "processing," lest the applicant become disgusted with apparently needless waste of time and change his mind. Prompt replies to inquiries and early action on applications would expedite procurement.

To summarize, I have suggested four means of increasing interest in the Army and, therefore, the number of physicians volunteering and entering the service:

1. Change tables of organization to provide for a greater proportion of higher grades in the Medical Corps.
2. Discontinue specialty "certification" requirements for commissions in grades above that of captain.
3. Institute a more liberal and uniform waiver policy as regards minor physical disabilities.
4. Afford more courteous, considerate, and prompt handling of procurement administration.

The foregoing comments, of course, are predicated upon the presumption that the Army needs a large number of additional medical officers, as would seem indicated by frequent appeals and editorials in the *J.A.M.A.*, and the recent announcement by the Director of Selective Service that a million men will be added to the armed forces during the next year.

Very truly yours,
CHARLES A. COLLINS, M.D.

ANNOUNCEMENT

All physicians who have been previously physically rejected for commissions in the Army or Navy should apply for re-examination at once, as the Services have changed their physical requirements and those previously rejected may now find that they are eligible for commissions.

COMMITTEE ON WAR PARTICIPATION
Medical Society of the State of New York

more often it seems to begin as impending shock, sometimes progressing slowly at first, then more and more rapidly, and invariably leading to death if its cause is not interrupted in time and if it is not counteracted in time by sufficient body mechanisms and reserves or by therapy.

Low blood pressure is considered both by clinicians and by many investigators as a *sine qua non* for the development of shock. From our early work on hemorrhagic and traumatic shock we concluded, however, that blood pressure is not a good index of the seriousness or of the prognosis of an animal in shock.[17] In one condition particularly—thermal trauma—we have found in the dog, cat, and rabbit,[18] and others have found in the human being,[19] that blood pressure may stay at or above normal for prolonged periods of time, while all other determinations and signs and symptoms indicate a grave condition of the experimental animal or of the patient.

In extensive work on shock following hemorrhage, trauma, and burns, we have observed that one of the best indices of the condition of the animal is the carbon dioxide content of the blood plasma.[21,24] This value indicates the degree of acidosis, which itself is a function of the intensity and duration of the tissue ischemia and anoxia.

Wiggers and his colleagues have recently reemphasized the importance of both the degree and the duration of hypotension in the development of irreversible shock following hemorrhage in dogs.[9,21] They have also described a technic of repeated bleeding which results in a state of shock from which the animals fail to recover when reinfused with the same amount, or more, of whole blood than was originally withdrawn. We feel that while Wiggers' method may be useful in developing a profound and irreversible type of shock, yet determinations of CO_2 in similar experiments may give a further indication of the condition of the animal at any particular moment. Moreover, the animal in irreversible shock is hardly the ideal test object for the study of the treatment of shock, for, by definition, nothing can halt its progress toward death. Practically, what we are seeking is an accurate and simple method of determining a stage intermediate between posthemorrhagic hypotension and irreversible shock—a stage from which the animal will die if inadequately or improperly treated, but from which he will recover with correct treatment.

Our experiments on shock were planned in such a way as to lead to the death of all of the untreated animals. Our procedure of producing shock by graded hemorrhage is as follows:[22,23] Total blood volume is calculated as one-thirteenth of the body weight. The unanesthetized dog is bled* 20 to 30 per cent of its estimated blood volume; one-half hour later an additional 10 to 20 per cent, and, if necessary, half an hour later an additional 10 per cent of the estimated blood volume are withdrawn. Determinations of the arterial plasma CO_2 are repeated at intervals and the infusion of the restoring fluid is administered at a particular plasma CO_2 level.

We have found the determination of the arterial plasma CO_2 to be the best method of evaluating the animal's condition in shock and predicting its response to various infusions. When the hemodynamic criteria of shock—hypotension, decreased pulse pressure, and increased circulating time—are present, we can be fairly certain that an animal with a moderately low plasma CO_2 content will not survive if untreated or infused with crystalloid solutions. However, we can be equally certain that he will survive if given iso-osmotic protein solutions, whereas an animal with an extremely low CO_2 generally will be in irreversible shock and will be dead the next morning even after what was apparently a complete recovery a few hours after infusion with iso-osmotic serum or plasma, and probably even whole blood.

Each restorative fluid is evaluated from the results of assays on a number of test animals at various levels of arterial plasma CO_2.[24-25] Numerous controls have shown that when the blood plasma CO_2 is below 10 volumes per cent, restoration is generally only temporary when even iso-osmotic protein solutions are administered. If the CO_2 is between 10 and 15 per cent, a few animals may survive following saline infusion, and many more will live with serum, plasma, or gelatin. At a CO_2 level between 15 and 20 per cent, a few animals will survive without therapy, and more will survive with saline infusion. Once these values have been established, it is relatively easy to evaluate any blood substitute. Because it is technically easier to lower the CO_2 level to 10 to 15 per cent without too high a mortality rate before therapeutic infusion, we have chosen this level as the critical one in our experiments. If a blood substitute can restore animals with plasma CO_2 between 10 and 15 per cent in the greater number of cases, we consider it good, because the mortality in this series, if untreated, or if treated with crystalloid solutions, is high. It should be stated here that the survival times of animals receiving therapeutic infusions of blood substitutes could be predicted with a fair degree of accuracy from the recovery of their plasma CO_2 values.[24-26]

Our studies on shock and blood substitutes have revealed that the state of hydration of the

* Under local anesthesia.

As a matter of fact, Wiggers and his colleagues have shown that such a selective area seems to exist in the upper small intestines, and they stress the occurrence of hemorrhagic changes in this area as a *sine qua non* for the evidence of whether an animal was in true shock following severe hemorrhage.[3,9] We have to assume here, however, that different areas must have a different sensitivity to anoxia. This question of selective sensitivity is supported by observations on hemorrhagic shock by Knisely and his associates. They found a practically complete cessation of capillary circulation through striated and smooth musculature and a persistence of capillary circulation through only a few vital organs.[2] Arteriovenous anastomoses may have played a role in shunting the blood back to the veins from the areas with capillary constriction (vide infra-).

The skin is evidently the one system with most evident and prolonged vasoconstriction during most conditions of shock. Yet no histologic changes in the skin of human beings or animals in shock have been described.[3] On the other hand, hemorrhagic changes in the small intestines have been observed by our group and by many others.[3] The capillaries of the intestinal mucosa and the mucosa itself seem to be most sensitive to anoxia.

In the consideration of peripheral resistance and of widespread constriction of arterioles and capillary areas, one important physiologic factor generally has been neglected—namely, anastomoses between arteries and veins, the so-called arteriovenous anastomoses. It is known that these anastomoses occur in many parts of the body and are particularly numerous in the small intestine.[10,11] It is believed that they serve a purposeful end in shunting the blood directly from the arteries into the veins in such areas in which metabolism is temporarily low, thereby saving the cardiovascular system an unnecessary amount of work.[10,11] An opening and closing mechanism has been described for these anastomoses. Heat, cold, ultraviolet radiation, and drugs like histamine, lactic acid, and atropine have been described to open these sphincters, and adrenalin, morphine, pituitrin, and ergotamine to close them.[10–15] External heat can open so many anastomoses that the venous blood of the arm may appear arterial in color and have increased pressure and pulsation.[10,11]

The diameter of the anastomoses is considerably wider than that of the capillaries of the same region, and the connecting veins are particularly thin-walled and large. If in a large area of the body these anastomoses should stay closed for some time, the peripheral resistance of this area would be maintained. If, on the other hand, these anastomoses would stay open in a large area, the peripheral resistance of this area would be low. At the same time, the capillary bed in this region would be anoxemic for a period of time and the capillaries might become permeable to plasma and finally to red cells. Penner and Bernheim,[15] and Klemperer and associates[16] have assumed a similar mechanism together with arteriolar constriction to play a role in the development of ulcers and of inflammatory and hemorrhagic changes in the intestines during the terminal stages of various diseases. Their work may have an important bearing on the vascular mechanics of shock in general.

If in a large area like the splanchnic bed the arteriovenous anastomoses would open and if, furthermore, no vascular area comparable in size to the splanchnic one would compensate by vasoconstriction, systemic blood pressure would drop to low levels; at the same time, venous return to the heart would increase at first, and even after some loss of plasma has occurred it may not show much change for some time, a fact which has been found to occur in shock and which has puzzled observers.[3]

We do not know, as yet, enough about the normal physiology and particularly about the innervation of the arteriovenous anastomoses,[13] nor enough about their pathologic physiology during shock, and we therefore, cannot draw any definite conclusions. We want to stress, however, that further knowledge of this important link in the circulation would be of greatest importance for the understanding of shock. An increase or a decrease of total peripheral resistance may mean little when we think of the possibility that large areas, such as the splanchnic bed, may have an increased rate of blood flow and yet may be anoxic for prolonged periods of time because of an opening of the arteriovenous anastomoses, while another area, like the skin, may compensate by vasoconstriction, with the result that there may be no important change in the total peripheral resistance. Thus, the more important thing to know is whether large and susceptible (vide supra-) areas of the body may be anoxic for prolonged periods of time.

An additional factor to be considered in the mechanism of shock is the venous sphincters of the intestines and of the liver. The occurrence and distribution of both the arteriovenous anastomoses as well as the venous sphincters, vary in different animals. This latter fact has to be considered seriously in the interpretation and comparison of the results of experiments and observations in different animals and in man.[15,16]

We know one thing for sure about shock—that it is not a static condition but a dynamic and, in its advanced stages, a rapidly progressive condition. It may begin with primary shock, but

total calculated plasma proteins before the burn. Another fact is worth mentioning: although both patients were on a high protein-vitamin-caloric diet after the third day of the burn, their total blood proteins stayed at low levels (ten to thirteen days after the burn). We wonder whether protein absorption or utilization was impaired. However, stools were normal, and the urine contained only a trace of albumin for a few days. We believe that serum therapy saved these patients from ultimate irreversible shock. On the basis of this and of previous experience[17] we have suggested a modification of Harkin's formula for the treatment of burns, which Dr. Levinson will describe. On the fifth day after the burn a high degree of anemia developed which made it advisable to administer whole blood. The cause of this anemia of burns is not known as yet. We are trying to investigate this phenomenon in dogs in which, so far, we have found the same late occurrence of anemia.

In a few burn cases, analyses of the blister fluid and of the blood plasma were carried out simultaneously.[29] Total plasma proteins and the albumin/globulin content and ratio were determined in both. The interesting result was that the albumin content in the blister fluid was fairly constant, approximating that of the blood, but that the globulin content showed marked variations. It may be low, but it may be high, and was usually independent of the albumin level of the blood or of the blister fluid. Again, with progressively greater degrees of capillary damage, more of the larger globulin molecules can escape from the circulation.

The assumption of basic unity, a single cause for various similar events, has ever been one of the outstanding human traits—sometimes for the good and sometimes for the bad.

Many of us have looked for a common primary cause for shock produced by any of the various methods of the experimentalist or by nature. Moon and others[1,28] felt that the posthemorrhagic condition was not true shock and omitted it from their system. Blalock,[30] Wiggers,[3,9] our group,[23] and others[1] have shown conclusively that a true posthemorrhagic shock can occur. Wiggers[3] has called our attention to the possibility that the primary cause of shock following various events or procedures may not always be the same.

In our own work, we have seen many different phenomena occurring in groups of experiments in which shock was produced in animals by various methods, such as hemorrhage, traumatization, and burns. These differences may be side issues, and shock yet may have been due to a common factor. On the other hand, the differences may point to fundamental dissimilarities of the primary cause of the shock in each of the groups of experiments.

Following simple hemorrhage as the capillary pressure falls, extravascular water shifts into the circulation rapidly, and, since initially red cells and plasma had been removed in the same proportion, now the red cell concentration decreases —i.e., hemodilution occurs. It is only during the later stage that the hemoconcentration, typical to most other pictures of shock, develops. It is apparent that shock begins at a rather advanced stage of hypotension with acidosis, slowed circulation, etc.

Following severe traumatization, hemoconcentration develops quickly and progresses rapidly. In this condition much blood may be lost into the traumatized tissues, but ultimately more plasma than red cells is lost locally so that generally hemoconcentration then sets in. In the early stages, however, a hemodilution is not uncommon. Could a nervous or reflex factor play a primary role?

Following severe burns, with the animal in a grave state of shock, as indicated by acidosis, slow circulation, and hemoconcentration, blood pressure is either normal or elevated for prolonged periods of time; this is in contrast to the conditions of shock produced by other means. Gastrointestinal motility is greatly increased and gastric secretion and acidity may be augmented. This is in contrast to traumatic shock in which no appreciable change or depression of gastrointestinal functions occurred.[31,32] If a limb is burned after denervation, blood pressure either falls or else does not rise, as in typical experiments on innervated limbs. We have found that the rise of blood pressure following burns is apparently due to a number of factors—reflex, hormonal, and toxic (hemolysis). The latter, hemolysis, rarely occurred to any significant extent following anesthetic, drug, traumatic, or posthemorrhagic shock, but it was a common occurrence in burns.[18]

Thus we may conjecture that the primary, initiating mechanisms of shock may be different, but that eventually they all may lead to a common final picture.

The experimental approach to a finer differentiation of these different mechanisms is difficult but not impossible. With some of the best laboratories of the world working actively in this field, the solution of these problems may be one of the great contributions to mankind arising from this war.

experimental animal or the human patient may be a deciding factor in the prognosis of shock.[23–26] This is of importance particularly in this war, where much of the fighting takes place in excessively hot regions and in mechanized equipment, where dehydration owing to lack of water, excessive sweating, etc., may occur frequently. We have found a seasonal variation in the susceptibility of our animals to hemorrhagic shock, due apparently to a better state of hydration during the cold season. We have found it necessary, therefore, to conduct control experiments throughout the year and not to rely on older control series in the assay of each particular blood substitute. This is a factor, not reported and apparently not heeded by other investigators.

In our studies we have found that even normal, nondehydrated animals will not withstand infusion of concentrated solutions during shock as well as isotonic plasma or serum containing the same amounts of proteins. In dehydrated animals in more severe degrees of shock, the response to isotonic solutions is not so good as the response in well-hydrated animals, but it is still fairly satisfactory. Dehydrated animals in various degrees of shock, receiving concentrated solutions of albumin, plasma, or serum, exhibit neither as satisfactory a recovery of blood pressure and plasma CO_2, nor as good survival times as normally hydrated animals infused with the same solutions. The cardiovascular system apparently is subjected to a considerable strain during and shortly after the infusion of concentrated solutions; pulse pressure is increased, and the heart seems to pump against a greater resistance, probably against the increased viscosity of the blood caused by the administration of concentrated solutions. Furthermore, we and others have noticed that the administration of the considerable amounts of sodium citrate solution contained in concentrated plasma may lead to hypocalcemic tetany, an undesirable factor in animals or human beings in severe shock.[25]

These disadvantages of concentrated plasma protein solutions, particularly in dehydrated animals or human beings in shock, can, I believe, be explained satisfactorily. During and following hemorrhage, extravascular fluid reserves shift into the circulation. One of the first signs following hemorrhage is a dilution of the blood, indicating this process. During uncomplicated hemorrhage, this tendency to draw fluid into the circulation and thus to dilute the blood may persist over considerable periods of time, depending upon the water reserve of the individual animal.

When these fluid reserves are exhausted, however, because of prolonged or recurring hemorrhage, and when the condition of shock is serious enough, hemoconcentration begins to develop. In other words, the animal continues to lose fluid but cannot draw fluid back into the circulation. At this point, in animals subjected to repeated hemorrhage, the classical picture of shock, as described by Moon and others,[1,27] develops.

The use of concentrated solutions of plasma, serum, or albumin in cases of shock has been based on the assumption that fluid should be withdrawn from the extravascular fluid reserves or from areas into which it had been lost through capillary trauma or leakage. If the extravascular water reserves of the body are exhausted, or if an extensive loss of fluid into a traumatized area has interfered with circulation to such a degree that reabsorption is hardly possible, we no longer can expect these solutions to have good effects. In fact, in such cases fluid will be withdrawn from vital centers already damaged by prolonged tissue ischemia and anoxia[24] and death from internal, extravascular dehydration may occur despite a fairly good plasma volume. We feel, therefore, that we are safe in warning the profession against using concentrated solutions in severe shock, particularly when dehydration may be present.

In numerous experiments we have studied the fluid and protein shifts in hemorrhagic shock before and after infusion of various substances.[28] It has been found that small but significant amounts of albumin may shift in and out of the circulation rather rapidly. However, in conditions in which capillary damage is more severe, the larger globulin molecule escapes from the circulation, too.

We have followed protein shifts in a few patients with 45 to 50 per cent of their body surfaces severely burned.[29] These patients were in shock. They were losing plasma continually, as indicated by recurring hemoconcentration. During this process of hemoconcentration, blood pressures did not change appreciably and gave no reliable indication of the condition of the patients.

We were surprised to find that large infusions with human serum, which, during the first twenty hours amounted to more than the total calculated blood volume of these patients, did not permanently restore the plasma volume. It seems that the amount of plasma protein and of water lost from the blood and from the tissues was so considerable that the large amounts of infused proteins and of water were utilized for repletion of plasma and of organ fluid and protein levels, and hemoconcentration tended to develop again and again within the next two to three days.

One of these patients received 92 Gm. and the other 143 Gm. of serum proteins in excess of the

to prepare new rubber tubing at the Serum Center:

1. Boil twenty minutes in 4 per cent C.P. sodium hydroxide solution.
2. Rinse with tap water under pressure for one minute.
3. Boil ten minutes in 0.5 per cent C.P. acetic acid solution.
4. Rinse with tap water under pressure.
5. Boil twenty minutes in distilled water.
6. Rinse thoroughly with distilled water under pressure.

Used rubber tubing should be discarded when it becomes dark and discolored because of possible deterioration. The safety of rubber tubing becomes questionable after 10 preparations; tubing should never be used after 15 preparations. Used rubber tubing is cleaned as follows:

1. Rinse with tap water under pressure and inspect tubing from time to time under a strong light to see that all foreign debris has been removed.
2. Boil twenty minutes in distilled water.
3. Rinse thoroughly with distilled water.

Glassware.—After preliminary rinsing in tap water, glassware is cleaned by immersion in standard acid cleaning solution† for at least four hours. This is followed by thorough rinsing with tap water and finally distilled water. All traces of acid or alkali (soap) must be removed in washing glassware or other equipment because these substances can denature plasma proteins and cause reactions when plasma is given intravenously. It is also of paramount importance to protect clean equipment from exposure to dust. Dust may contain thermostabile pyrogenic substances.

Needles.—Immediately after use, needles should be thoroughly rinsed by forcing tap water through them. After preliminary flushing with water, stainless-steel bleeding needles are cleaned by quickly rinsing them with fuming nitric acid (diluted with equal parts of water) two or three times with the aid of a syringe. The needles are then immediately rinsed with several changes of water and finally with distilled water, alcohol, and ether. A fine oilstone is used for sharpening and pointing needles. Since smaller needles cannot be cleaned by means of acid, a stylet is used, and the needles are thoroughly flushed with water and rinsed in alcohol and ether.

Metal Parts.—Stainless-steel mesh filters and other metal parts are easily cleaned by boiling in 5 per cent sodium hydroxide solution for fifteen minutes, followed by boiling in 0.5 per cent acetic acid and thoroughly rinsing with distilled water.

† Five per cent technical sodium bichromate solution dissolved in concentrated sulfuric acid.

Berkefeld Filters.—Large Berkefeld candles are cleaned at the Serum Center by the following procedure:

1. Scrub surface vigorously with a fine brush within one hour after use or scrape surface lightly with the edge of a glass slide.
2. Filter through 2 liters of tap water.
3. Invert candle in a large test tube containing sufficient 0.85 per cent salt solution to cover filter and store at 5 C. for five to seven days.
4. Filter through 4 liters of 0.85 per cent salt solution.
5. Boil in 5 per cent sodium bicarbonate solution for one and one-half hours.
6. Boil twice in distilled water for one hour.
7. Filter through 2 liters of distilled water.
8. Dry in hot-air oven at 160 C. for six hours.

Pyrogen Test.—In order to reduce the incidence of reactions, routine pyrogen tests should be carried out with periodic samples of distilled water and the final washings in each batch of rubber tubing. (Full details of the technic are given in the U.S. Pharmacopeia XII, pages 606 to 607.) Briefly, this test consists of preparing a sterile sample of the test material in an isotonic solution of sodium chloride which is warmed to approximately 37 C. and injected intravenously into the marginal ear vein of at least 5 rabbits. Ten cubic centimeters of material per kilogram of rabbit is injected with a sterile and pyrogen-free syringe and needle. Rectal temperatures are taken fifteen minutes prior to inoculation and thereafter at hourly intervals until three recordings are made. The test is considered positive if 3 or more of the 5 animals show an individual rise in temperature of 0.6 C. (1 F.) or more above the normal established for each of these animals. If only 1 or 2 of the 5 rabbits show a positive response, the test must be repeated on a second group of 5 additional animals.

Sterilization.—Glassware is sterilized by dry heat at 180 C. for two hours. Syringes and apparatus employing rubber connections are sterilized in an autoclave by steam at 15 to 20 pounds pressure for thirty minutes in order to insure thorough penetration. The temperature must be at least 121.6 C. Glassware may also be sterilized in the autoclave and then dried by allowing steam to remain in the outer jacket with the steam cut off from the sterilizing chamber. Blood collecting sets and similar apparatus are double wrapped in heavy cloth before sterilization in order to remain sterile until used. Immediately after sterilization equipment should be labeled in order to prevent confusion with unsterile materials. The autoclave and hot-air

LABORATORY ASPECTS OF THE PREPARATION AND BIOLOGIC CONTROL OF PLASMA

ALBERT MILZER, M.S., Ph.D., Chicago

PLASMA is the liquid constituent of blood which has been prevented from clotting by the addition of an anticoagulant, usually sodium citrate. Serum, on the other hand, is the liquid which separates from blood that has been permitted to clot spontaneously. Essentially, plasma is a sterile solution containing various salts, albumin, globulin, and fibrinogen.[1] Freshly prepared plasma contains no visible particles and is free of cellular elements, except for a variable number of blood platelets. A precipitate of fibrin usually develops when plasma stands, and it must be filtered before use. Serum can be used without preliminary filtration because fibrin precipitates do not occur. Moreover, serum contains no sodium citrate solution and is, therefore, cubic centimeter for cubic centimeter, more effective than plasma. According to Best and Solandt,[2] properly prepared plasma and serum are physiologically and therapeutically identical and may be used interchangeably as a blood substitute in the treatment of shock and hemorrhage.

The preparation of plasma or serum requires great care. The minimum requirements as set forth by the National Institute of Health should be scrupulously observed in order to prepare a sterile product free of reaction-producing substances. Plasma is easier to process than serum. For this reason, and because the preparation of serum is limited to specially trained personnel, this paper deals principally with plasma.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943. Part of a Symposium on Plasma.

From the Samuel Deutsch Serum Center of Michael Reese Hospital and Michael Reese Research Foundation, Chicago.

*Preparation of Equipment**

All items of equipment used in preparation must be chemically clean as well as sterile. Only pyrogen-free, freshly distilled water should be used for washing rubber parts and glassware used in the preparation of solutions for intravenous use. A known pyrogen-free sodium citrate should be used as the anticoagulant. Pyrogen (fever- and chill-producing) reactions are caused by the intravenous injection of solutions containing any of the following: (1) filterable thermostabile products of growth of certain strains of bacteria, (2) certain strains of dead bacteria, (3) traces of other foreign protein matter, and possibly (4) nonprotein particulate matter, such as powders from new rubber tubing.[3–6]

Rubber Parts.—New rubber stoppers are prepared by boiling in 4 per cent sodium hydroxide solution, immersion in boiling 0.5 per cent acetic acid solution, and rinsing with distilled water. Used rubber stoppers are scrubbed with soap and water and rinsed thoroughly with distilled water. Rubber tubing must be carefully cleaned because many pyrogenic reactions can be traced to inadequately cleaned tubing. Foreign protein matter, such as old blood clots, has often been incriminated. The following procedure is used

* I am indebted to Mr. John Moss for details on preparation of equipment at the Serum Center.

FIG. 1. Tubes of thioglycolate medium inoculated with plasma contrasting bacterial growth with various precipitates in the medium. Reading left to right: tube 1—surface growth and amorphous precipitate near bottom; tube 2—no growth, amorphous precipitate near bottom; tube 3—no growth, crystalline precipitate near bottom; tube 4—diffuse growth; tube 5—surface growth and amorphous precipitate near bottom; tube 6—diffuse growth with greatest concentration near bottom.

multiply, but somewhat more slowly in plasma that is kept at 5 C. After rather extensive studies, Mackay[12] concludes that disinfectants have only a limited value in controlling bacterial growth in stored serum. Smith, Czarnetsky, and Mudd[13] have shown that serum proteins rapidly neutralize the bactericidal effect of merthiolate and other mercurial preservatives. The possibility of using a combination of 1:20,000 merthiolate and 0.25 per cent phenol as a preservative[14,15] because this mixture will destroy the usual contaminants of plasma is not favored by the Board of Medical Control of Plasma for England.[7] They point out that toxic amounts of phenol would be given in large plasma transfusions (7.5 Gm. of phenol in 3 liters of plasma). At present the following preservatives and concentrations are recommended by the National Institute of Health: (1) for liquid or frozen plasma, a final concentration of 1.10,000 merthiolate or 1:15,000 phenyl mercuric borate, and (2) for dried plasma, a final concentration of 1 35,000 merthiolate or 1:50,000 phenyl mercuric borate.

After the addition of the preservative, the plasma pool may be filtered through a Berkefeld N filter for clarification and, as an added precaution, to eliminate chance contamination. When plasma is processed, Berkefeld filtration is not required nor is it usually employed because the presence of fibrin makes filtration a difficult procedure. The pooled plasma is next bottled through a closed system in sterile containers suitable for administration to the recipient in 300 cc. amounts by means of a buret. If the plasma has not been filtered prior to bottling, the lumen of the filling tube leading to the final container must be fitted with a filter adequate to remove

sterilizer should be equipped with a recording thermometer.

In operating an autoclave, it is extremely important to keep the sterilizing chamber free of air during the period when steam enters the chamber. This can be accomplished by keeping the drain valve slightly open. Failure to expel air results in a marked decrease in temperature although the pressure gage may indicate the desired reading.

Processing of Plasma

Plasma Processing Room.—Plasma should be prepared in dust-free rooms in order to reduce the incidence of bacterial contamination. As an additional precaution technicians should wear sterile gowns, caps, shoe coverings, and masks. Complete details of a well-equipped plasma processing room are given in the "Report of the Blood Transfusion Association Concerning the Project for Supplying Blood Plasma to England."[7]

The plasma processing rooms at the Serum Center are equipped with refrigerated air conditioning units and water sprinklers so that the rooms can be routinely showered down after each day's work. The success of these rooms in minimizing air contamination is reflected in the relatively low bacterial count of plates exposed twice daily for thirty minutes. The count usually varies from 0 to 4 colonies per plate. Our experience with several makes of commercial ultraviolet radiation units for reducing the bacterial count of air in the processing rooms has been disappointing. We feel that many airborne bacteria within particles of dust and mucus are protected from the action of ultraviolet rays, which have very limited powers of penetration. The use of propylene glycol and other germicidal aerosols for air sterilization in plasma processing rooms is a promising possibility that awaits further development.[8]

Collection of Blood.—Only healthy persons, certified by a qualified physician as being free from any disease transmissible by blood transfusion at the time of bleeding, may serve as donors. A specimen of blood is taken from the collecting tube at the time of bleeding to be tested for syphilis by an acceptable serologic test. Bloods showing a 3 or 4 plus reaction are discarded. Those showing doubtful results (plus-minus, 1 or 2 plus reaction) are checked by another method, preferably a complement fixation test. If the same degree of reaction, or less, is obtained, the blood may be processed. If, however, the retest method is a complement fixation test, any blood giving a 2 plus reaction is discarded.

The technic of bleeding is as follows:

1. Adjust tourniquet or blood pressure cuff.
2. Prepare skin with iodine and alcohol.
3. Produce local anesthesia over vein with 2 per cent novocain.
4. After venipuncture, apply slight suction and withdraw blood into an individual sterile centrifuge bottle already containing 50 cc. of a sterile 4 per cent solution of sodium citrate in 0.85 per cent sodium chloride for each 500 cc. of whole blood.
5. Within one hour after bleeding, place the citrated blood in a refrigerator kept at 2 to 5 C. Freezing must be avoided, or laking of the erythrocytes will occur.

Preparation of Plasma.—Usually within twenty-four hours after bleeding (not longer than seventy-two hours), the citrated blood is removed from the refrigerator and centrifuged at 2,000 r.p.m. for twenty minutes in order to produce thorough packing of the cells. The supernatant cell-free plasma is then withdrawn into a sterile individual bottle through a closed system. A closed system is defined as one in which the air of the room is not allowed to come in contact with the plasma, except as air for replacement, and this air must pass through an antibacterial air filter. All transfers of plasma from one container to another are made through a closed system in a dust-free room. At the Serum Center each individual plasma is tested bacteriologically as well as serologically before pooling. If the tests are negative, eight or more individual plasmas are pooled in a large container in order to suppress the iso-agglutinins.[9] Each individual plasma is poured into the pooling bottle through a large filtering funnel lined with four to six layers of finely meshed gauze in order to remove as much fibrin as possible. The completed pool should not contain more than 25 mg. of hemoglobin per 100 cc. A sufficient amount of 50 per cent dextrose solution to give a final concentration of 5 per cent dextrose is then added to the plasma pool intended to be dispensed in the liquid or frozen state without subsequent drying. Dextrose serves as a stabilizing agent and inhibits fibrin formation.[10] No dextrose is added to plasma that is intended for drying.

Before adding a preservative to the pool, a sample is withdrawn for a sterility test. The preservative is then added to insure additional safety by prohibiting the growth of chance contaminants. Unfortunately, no suitable preservative is known which will insure the sterility of plasma against all types of contaminants found in biologic products. Some of the common contaminants usually encountered in plasma include diphtheroids, staphylococci, nonhemolytic streptococci, hay bacilli, and Pseudomonas pyocyanea.[11] All of these organisms grow readily in plasma stored at room temperature, and many

tamination, then a completely filled final container is selected at random and cultured. The plasma of the pool under test may be released for use if the random final container is sterile; otherwise the entire pool is discarded. The sterility test on the final containers of frozen plasma is carried out in the same manner after thawing the samples in a water bath at 37 C. In the case of dried plasma, a sample of 10 cc. instead of 20 cc. is withdrawn from the dried sample reconstituted to its orginal volume by the addition of sterile distilled water for culturing.

Safety Tests.—Each pool of plasma is tested for toxicity by inoculating the final product intraperitoneally (0.5 cc.) into a mouse and subcutaneously (1.5 cc.) into a guinea pig. Daily temperature and weight records are kept on the guinea pig, and the animals are observed for one week. If either animal dies, additional animals are inoculated and if these survive and show no toxic symptoms the first death is disregarded.

Dating and Storage of Plasma.—Liquid plasma should be stored at a fairly constant room temperature within the range of 15 to 30 C., and the expiration date should not exceed one year from the date of manufacture. Liquid plasma should not be stored in the refrigerator because lower temperatures increase precipitation. Frozen plasma is stored continuously at −18 C., or lower, and its expiration date should not exceed three years from the date of manufacture. Frozen plasma is thawed in a constant-temperature water bath at 37 C. Dried plasma is preferably stored in a cool place and expires five years from the date of manufacture.

Records.—The keeping of accurate records is an important part of the successful preparation of plasma. Permanent records are kept of the name, sex, age, address, medical history, blood group, etc., of each donor comprising the pool. Each pool is given a lot number, and permanent records are made of the date of preparation and the results of sterility and animal safety tests.

Conclusions

The preparation and biologic control of plasma requires great care. It is recommended that the rules of the National Institute of Health for the preparation of normal human plasma be observed in order to prepare a safe, sterile product free of pyrogenic substances. All items of equipment must be chemically clean as well as sterile. A rigid aseptic technic should be followed in collecting the blood, and a closed system in a dust-free room should be employed during all stages of the processing of plasma. Sterility tests should be made on the individual plasma and on random final containers after pooling. An animal safety test should be made of each pool and careful permanent records kept of every aspect of preparation.

PRINCIPLES AND METHODS OF DESICCATION OF PLASMA

FRANZ OPPENHEIMER, Ph.D., Chicago

THE practice of drying materials from the frozen state is a long-established laboratory procedure. D'Arsonval's discovery of a method to liquefy air made it possible to create a very high vacuum in a system containing water. As early as 1906, d'Arsonval and Bordas described such vacuum desiccation and the drying of frozen organic materials. The apparatus consisted of two connected chambers, one serving as a container for the frozen material, the other functioning as a condenser for the water vapor and cooled by liquid air or carbon dioxide snow-acetone mixture (Diagram I). This method has been a commonly known laboratory procedure, used whenever the occasion required the drying of material out of the frozen state. The entire system was thoroughly evacuated, and the vapor

From the Samuel Deutsch Serum Center and Michael Reese Research Foundation, Chicago.

all coarse particles that would be dangerous if administered intravenously. As an additional safety measure, the plasma must be filtered again just before administration. When processing plasma to the liquid or frozen state, the final containers must be filled within twenty-four hours after completion of the sterility tests on the individual containers or on the pool (see next section). Plasma which is to be processed to the frozen state is placed in a freezing compartment immediately after the container is filled and brought to the frozen state within six hours. For processing plasma to the dried state, the final containers must be shell frozen within seventy-two hours of bleeding.

Sterility Tests.—A fluid thioglycolate medium such as the Linden or Brewer formula[16] is recommended by the National Institute of Health for making sterility tests on plasma and other biologics. Thioglycolate medium has the great advantage of supporting the growth of anaerobic as well as aerobic bacteria. This medium maintains anaerobic conditions without the use of seals and does not require boiling immediately before inoculation. Moreover, the thioglycolate present in the medium combines with and neutralizes merthiolate and most other mercurials used as preservatives. Repeated tests have shown that 7.5 cc. of thioglycolate medium is ample to neutralize the bacteriostatic effect of 1 cc. of plasma containing 1:10,000 merthiolate or phenyl mercuric borate.

Like others, thioglycolate medium has its disadvantages. In reading sterility tests one often sees various amorphous and crystalline precipitates which are sometimes very similar to bacterial growth (Fig. 1). Most of the amorphous precipitates are probably caused by the settling out of small amounts of agar which is an essential ingredient for maintaining anaerobiosis in the medium. We have found that these precipitates can be avoided to some extent if the thioglycolate medium is stored in the incubator immediately after autoclaving. Thioglycolate medium should not be stored in a refrigerator because the duration of anaerobiosis is decreased.[16] A lower temperature increases the solubility of atmospheric gases in the medium. Another disadvantage is that certain organisms tend to grow in discrete colonies, especially if fibrin veils are present, and growth does not spread throughout the medium. Except for these disadvantages, fluid thioglycolate has been very satisfactory in our hands for culturing plasma and other biologics. We tube 15 cc. of medium in test tubes 6 inches by $^5/_8$ inch and autoclave for twenty minutes at 121.6 C. Each test tube is covered with a close-fitting glass cap, and 10 tubes are kept in a rack. Thioglycolate medium is commercially available in the dehydrated form and may be purchased from the Difco or Baltimore Biological Laboratories.

The regulations of the National Institute of Health require tests for sterility on plasma from (*a*) each individual bleeding or from a sample taken from the plasma pool prior to the addition of a preservative, and (*b*) on a specified number of final containers. For sterility tests on individual bleedings of plasma processed to the liquid or frozen state, a 5 cc. sample is withdrawn from each individual plasma and cultured at 37 C. for seven days in one or more portions of thioglycolate medium. We add 2 cc. of plasma to each culture tube containing 15 cc. of medium. If growth occurs, the plasma is discarded, or it may be retested and discarded if contamination appears in the retest. When plasma is to be processed to the dried state, a test sample of only 2 cc. is withdrawn from each individual plasma for the sterility test. A forty-eight-hour reading of the sterility test is required because plasma intended for drying is pooled at that time and brought to the frozen state within seventy-two hours of bleeding. For several reasons, we prefer to culture the individual plasmas before pooling. First, the chances of recovering organisms from low-grade contaminations are increased, since the dilution factor in pooling is eliminated. Second, one contaminated individual plasma can result in the loss of an entire pool, and, finally, a large number of individual plasmas can be pooled with a greater degree of safety.

If the sterility test on the pool prior to the addition of the preservative is elected instead of the individual bleeding, two separate samples of 20 cc. (only 5 cc. if the plasma is intended for drying) must be drawn. One of the samples is planted in one or more portions of thioglycolate medium. If contaminated, the test is repeated with the second sample. The pool is discarded if growth occurs in the retest.

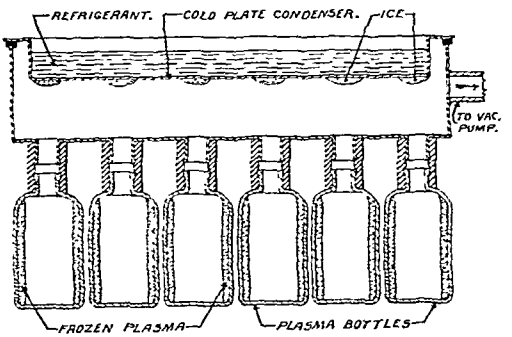
Before making the sterility test on the final containers, liquid plasma must be stored at room temperature (60 to 80 F.) for at least two weeks from the time of filling the containers with the plasma pool. For each pool of 25 final containers the first 25 cc. flowing from the plasma reservoir and the last 25 cc. are drawn into a single random final container. If the pool is larger, an additional sample is withdrawn for each 25 final containers just before and immediately after each group of 25 final containers. After storage for two weeks, the sample is allowed to come in contact with the entire inside surface of the container, and 20 cc. is withdrawn for the sterility test. Should growth occur in any tube planted, the sterility test is repeated with the unused portion of the sample. If the retest also shows con-

with a gage which records the total pressure in the system—i.e., both air and water vapor pressure.

The commonly used McLeod gage measures only air pressure, and therefore it is necessary to use a gage of the heated thermocouple type or a heated resistance wire which measures the water vapor pressure as well.

Ice will sublimate in a vacuum of 1 mm. Hg at −17 C., at 500 microns (1/2 of 1 mm. Hg) at −24 C., 250 microns at −31 C., and 100 microns at −40 C. Any good vacuum pump will create and maintain a high air vacuum, 50 to 100 Hg microns being sufficient. The drying of frozen materials does not present a static system, but a dynamic one. The sublimation constantly produces water vapor, the amount depending on the rate at which heat of sublimation is introduced. This water vapor must be rapidly removed from the system; otherwise the vacuum will spoil and the plasma will melt. The movement of the water vapor from the bottle to the condenser is only by diffusion, which is naturally a slow process. Therefore, it is imperative to avoid any hindrance to this vapor flow.

In order to insure sterility, it is required to dry plasma in its final container, a bottle; the bottle neck of the container constitutes a restriction to vapor flow and causes an unavoidable but serious deviation from the ideal condition. Since plasma must be dried in a bottle, the neck should be as large as possible because the flow through a bottle neck is directly proportional to the third power of the diameter. All connections between drying chamber and condenser should be as short as possible and of large diameter. A combined drying and condensing chamber is a very efficient system.



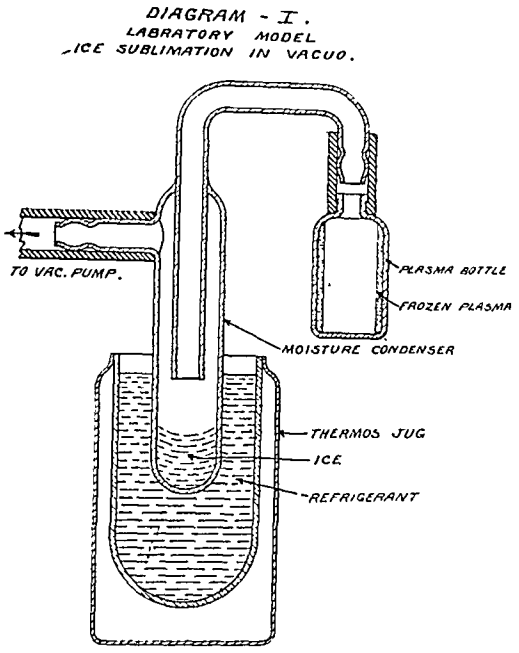
One of the attempts to produce large amounts of dried plasma was by a direct and simple enlargement of the original laboratory model, which is illustrated schematically in Diagram II. This shows a combination of drying and condensing chamber, eliminating all restrictions to vapor flow except the one of the bottle neck, and bringing the condensing surface in close proximity to the source of vapor production. Thus a good vacuum can be easily maintained. In principle this is an effective and fairly practical method, but it is rather laborious and relatively costly in maintenance.

Modifications of the apparatus shown in Diagram II are easily constructed, relatively inexpensive, and are in use.

Condenser

The efficiency of the condenser in reconverting the water vapor to ice is an important factor in maintaining a good vacuum in the system. From the preceding discussion on the importance of a maintained vacuum for proper desiccation of plasma, the condenser for moisture removal occupies a prominent position in successful operation.

DIAGRAM − II.
SCHEMATIC PRODUCTION MODEL
ICE SUBLIMATION IN VACUO.



Oil pumps have been used for the dual function of producing an air vacuum and removing the water vapor by condensing it in the oil. The oil and water are then separated by a centrifugal arrangement. This attempt has not proved successful for large-scale production because the process is slow, a high vacuum can never be obtained, and the drying takes place at temperatures dangerously close to the melting point of the plasma.

Another method which relies upon the vacuum to remove both air and water vapor simultaneously is the steam ejector. The steam ejector is similar in principle to the common laboratory water aspirator. High-pressure steam (between 90 and 150 pounds) is forced through a very small nozzle, and the very rapidly expanding steam exhausts the air and water vapor, maintaining a good vacuum. By using multiple ejectors a very high vacuum can be obtained. This system is practical if high-pressure steam is available and if sufficient water can be used for the condensation of the steam. A large drying chamber can be employed and several hundred bottles of frozen plasma can be dried simultaneously.

This equipment is now in common use and is highly successful.

Cold surface condensers are much more effective provided the temperature is sufficiently low and the surface sufficiently large. It is not essential that the temperature of the condenser be as low as −70 C., for −30 to −50 C. is adequate if the surface is large and if this temperature is

of the frozen material slowly sublimed into the condenser.

There is no good terminology applied to this technic, and we propose the use of the term "drying by ice sublimation" to express accurately the fact that the material is converted from the frozen state directly to the dry, solid state, the water being converted from ice to steam without an intermediary liquid phase.

Just before the outbreak of World War II, investigators found human plasma and serum to be good substitutes for blood, particularly in shock and burns. It was obvious that plasma or serum dried by ice sublimation would offer great advantages in supplying large quantities of plasma to the armed forces. There are at least three definite advantages for the dried product: (1) it can be stored regardless of extreme climatic heat or cold to which it might be exposed in any part of the world, (2) the great stability of organic materials dried by ice sublimation permits at least five years' storage of plasma, and (3) the reduced shipping weight and thus decreased likelihood of breakage are added values in wartime.

These considerations prompted the decision to make available large amounts of dried plasma to the fighting forces, and the biologic industry was confronted with the difficult task of converting a laboratory process into large-scale production with little time for experimentation. It is, therefore, not surprising that the first production machines were constructed in such a manner that they violated some of the basic physical principles that govern drying by ice sublimation. These early machines required from one hundred to one hundred and twenty hours to dry plasma, and even then the moisture content of the dried product was relatively high. Furthermore, there was frequent melting in minute spots during the drying process, and the resultant drying from the liquid state produced a hard, granular product which redissolved slowly and with great difficulty. It should be stated here that in order to have maximum stability, the final water content of the dried powder should be less than 0.5 per cent.

A thorough appreciation of the fundamental principles is necessary to dry plasma properly by ice sublimation. Under ideal conditions, if the film of frozen material is infinitely thin, the surface infinitely large and unrestricted, the temperature constant and the vacuum perfect, the drying would be instantaneous. The farther one departs from these ideal conditions, however, the slower the drying process will be.

Shell Freezing

In order to provide the largest possible surface and the thinnest possible film in the bottle, the liquid plasma is frozen as a shell against the glass wall by rotating the bottle in a cold bath on its side.

The frozen shell should be a true cylinder. This can be accomplished by rotating the bottle on its side partly submerged in a refrigerant, preferably at 12 to 20 r. p. m., or spinning the bottle at a speed sufficiently high so that centrifugal force will throw the liquid against the walls of the bottle in the shape of a cylinder, and either submerging the rotating bottle in a cold bath or exposing it to very cold circulating air. The temperature of the freezing bath should be so low that very rapid or so-called "snap freezing" will occur. Otherwise the components of the plasma will separate by fractional crystallization, and the drying of plasma will be more difficult. The freezing bath should be maintained at −65 C., or lower, during the entire shell freezing process. Freezing at this temperature produces a very uniform and smooth cylinder of frozen plasma, while at higher temperatures the shell might be irregular and lumpy because of focal ice crystallization.

Vacuum

The degree of vacuum in the drying system is a very important factor, for it controls the temperature at which the sublimation will occur, just as the atmospheric pressure controls the boiling point of water. It should be measured

THE CLINICAL APPLICATION OF PLASMA

SIDNEY O. LEVINSON, M.D., Chicago

UNDER the impetus of this war, the field of plasma therapy has undergone a remarkably rapid expansion and application. This is best illustrated by recalling that the first preliminary reports on the use of human serum or plasma were published about five years ago.[1] In these last five years an astonishingly voluminous literature has appeared on this subject. Our prediction made in 1939[2] that "it [plasma] can be processed in ample quantities from the blood of noncombatants in civilian centers far removed from the war front, prepared in proper containers ready for use, and distributed directly to the front" has been borne out by the Red Cross Blood Plasma Program, whereby several million units are being made available to the fighting fronts all over the world from blood collected from civilians in this country.

There are certain facts that must be kept in mind in order to evaluate the position of plasma in therapy. Plasma in the body is the noncellular fraction of blood, consisting principally of water, 0.85 per cent salt and about 7 per cent protein made up chiefly of albumin and globulin. In vitro plasma also contains the anticoagulant employed when the blood is removed, usually sodium citrate solution. Serum is the liquid fraction expressed when blood coagulates and is undiluted true plasma from which most of the clotting constituents have been removed. For practical purposes serum and plasma are practically the same and produce the same result. They can be prepared in three different forms—liquid, frozen, and dried.

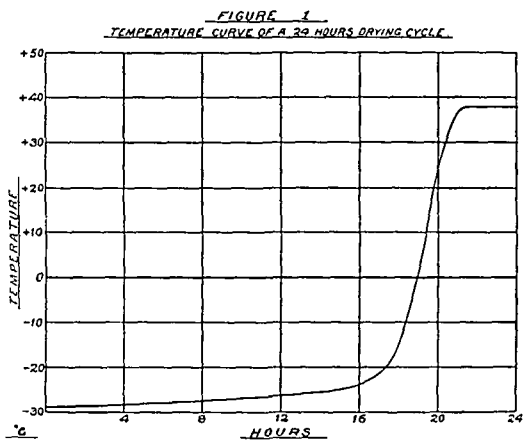
Circumstances dictate which form may be preferable. The liquid plasma, after preparation, should be stored at room temperature to prevent the formation of fibrin strands and precipitates. Liquid plasma should not be kept more than one year. It requires the least handling and is most readily available in emergencies. The liquid plasma, if frozen and stored at −20 C. or lower, is believed to remain stable for three years. It requires thawing at 37 C. before administration, with some attendant time loss. Properly dried plasma is believed to remain stable for at least five years, is not subject to deterioration by climatic extremes, and therefore does not require special equipment or special provision for storage. Restoration with distilled water and return to the liquid state before infusion takes from five to ten minutes if the plasma has been properly desiccated. There is one practical advantage of frozen or dried plasma. During processing, chance contamination may occur which may not appear on testing. Bacterial growth will be inhibited in the frozen or dried state, a distinct safety factor that does not exist with liquid plasma.

For ordinary civilian and hospital use, liquid plasma prepared by observing all the safeguards set up by the National Institute of Health should prove completely satisfactory because liquid plasma can easily be maintained at room temperature, requires no special drying or low temperature equipment, and is utilized within the specified one year. For use under difficult conditions in an indefinite period of time, as for war purposes, the dried form is the one of choice, and fully worth the additional effort required in desiccation.

A brief survey of the principal uses of blood transfusion will clarify the application and value of plasma. The succeeding discussion will be restricted to plasma. Consideration of other therapeutic measures is intentionally omitted with the understanding that sound basic surgical and medical measures and other adjuvant therapy is equally or more important in successful treatment.

Uses of Blood Transfusion

1. Anemia.—The deficiency is principally erythrocytes and only whole blood transfusion is indicated. Plasma is ineffective. Erythrocytes suspended in saline are being increasingly used with favorable results.[3]



2. Simple Hemorrhage.—In the absence of shock and ample time for treatment, whole blood is the preferred agent.

3. Extensive Hemorrhage with Shock.—Whole blood is the only complete therapeutic agent. Since shock may progress rapidly and since delay involved in blood transfusion must therefore be avoided, plasma finds a place as interim emergency therapy to correct the oligemia and combat the shock until whole blood can be administered to overcome the anemia resulting from the blood loss.

4. Traumatic and Surgical Shock.—One of the predominant features characterizing shock is deficient circulating fluid, owing to plasma loss. The sequellae of such oligemia are hypotension,

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943. Part of a Symposium on Plasma.

From the Samuel Deutsch Serum Center and the Michael Reese Research Foundation, Michael Reese Hospital, Chicago, Illinois.

maintained regardless of the amount of water vapor which must be condensed. Temperatures of −30 to −40 C. are actually preferable because mechanical refrigeration is more efficient and simpler, and water vapor pressure at these temperatures is low enough to permit a good vacuum.

It is always essential that the refrigeration should have ample capacity to remove rapidly the heat of condensation and crystallization.

Heat

Heat of sublimation must be supplied to the frozen material. In the apparatus as shown in Diagrams I and II, this sublimation heat is supplied by the surrounding air. Ice will condense on the bottles from the moisture in the air, and the heat thus supplied is utilized to sublimate ice out of the frozen plasma. With an apparatus of this kind, therefore, it is advisable to keep the room warm (around 50 C.) and the relative humidity high. Circulating the air will facilitate the heat exchange. The heat transfer to the frozen plasma through the glass of the bottle is slow, but no air currents can be directed against the bottle because the plasma adjacent to the wall will easily melt. Heat might be supplied by other convenient means, such as submerging the bottles in a bath kept at the necessary temperature during the different stages of the drying process.

The drying process of frozen plasma might be classified, figuratively speaking, as falling into three stages:

1. The *principle drying period*, during which about 90 per cent of the water is removed. The temperature of the plasma should not be permitted to rise above −15 C. If the temperature remains constant during this period, it signifies that the water vapor is condensed as rapidly as it is produced by sublimation.

2. The *intermediate drying period*, in which an additional 9 per cent of water is removed. During this period the temperature should be allowed to rise slowly and gradually to 35 to 40 C. (describing an S-shaped curve).

3. The *terminal drying period*, in which the last fraction of 1 per cent of moisture is removed, by maintaining the dry plasma for from three to four hours at temperatures between +45 and +55 C. The last residual moisture appears to be held more firmly.

A characteristic and illustrative temperature record is presented in Fig. 1.

The bottles containing the dried plasma should be sealed in vacuum or in an atmosphere of dry nitrogen.

The temperature of the drying plasma can be measured in many different ways, but dependable average readings are secured from a thermocouple suspended in the middle of the bottle and exposed to the escaping vapor. During the principal drying period the amount of heat which can be introduced is limited only by the fact that the layer of plasma adjacent to the wall might melt. In the intermediate period, sublimation heat can be supplied only slowly because plasma containing a high percentage of moisture is easily denatured if the temperature rises too fast. Such denatured plasma may be quite toxic. There should be a period of from two to four hours in which the plasma is brought from −15 C. to +20 C.

Our experiments have shown that completely dried plasma containing less than 0.5 per cent moisture can be heated with safety to as high a temperature as +80 C. In our studies, plasma subjected to 80 C. for two hours after complete drying, was unchanged, for it redissolved easily and the reconstituted plasma was nontoxic when injected into experimental animals.

It is a truly remarkable achievement that the American biologic industry has taken a laboratory process, which is complicated and meticulous, and has rapidly developed production methods so efficient that they are now supplying several million units of plasma per year to the armed forces.

There are many other materials to which drying by ice sublimation can be applied. Many biologics are unstable in liquid form, can be dried only by ice sublimation without loss of potency, and are quite stable in the dried state.

This field is a relatively new one, and many developments may be expected in the future.

1,000 cc. are required, and in severe conditions and grave shock, 3,000 to 5,000 cc. may be necessary in the first twenty-four hours after injury.

It is important to realize that continued plasma therapy is often necessary to maintain the blood volume at normal levels because of continued plasma loss for one reason or another. The patient's condition, pulse, blood pressure, and the laboratory determinations are the best guide for plasma requirements. The patient must, therefore, be closely observed for at least seventy-two hours after onset for signs of recurrent shock.

These essentials of massive and repeated plasma therapy are particularly applicable to severe burns, where the plasma loss may be tremendous. In the past it was felt that the extensive plasma loss in burns required equally large plasma replacement, and various formulas[13,14,15] of estimating the dose were proposed. Some of these formulas were complicated, others inaccurate and usually too low, approximately 500 cc. for 10 per cent body burn. Both animal experiments[16,17,18] and clinical studies[13,14,19] demonstrate that plasma loss is usually in excess of the amount. In our own studies [19,20] in patients, based principally on the plasma requirements to re-establish and maintain normal conditions and values, we found it necessary to give larger amounts. Our course of plasma therapy consists of the following, based upon 10 per cent body burn: immediate infusion of 600 cc.; additional 300 cc. during the first twenty-four hours; a further 300 cc. in the next forty-eight hours. Continued plasma therapy may be required. The foregoing is only a working formula and is varied (usually increased), particularly in severe and extensive burns.

In considering the value of plasma as a restorative agent and concentrating on its protein content, one should not become oblivious to its water component. When plasma is lost in shock, water as well as protein is lost. If body reserves permit, water can very rapidly be drawn into the circulation. If the individual, however, is dehydrated, and fluid stores depleted, it is equally important to replace water as well as to restore proteins in order that the already dehydrated tissues be spared injury from further dehydration.

Studies in our laboratory with various macromolecular therapeutic agents clearly demonstrate that in shock, under any condition, the total fluid volume of the infused agent is of great importance.[21,22,23,24,25] Concentrated solutions are completely effective only if given with sufficient fluid. This is most strikingly demonstrated in animals in a dehydrated state. In the presence of severe dehydration, four times concentrated protein solutions administered in small volume of fluid are followed by a response which is much less prompt and rarely as complete as is seen after administration of protein equivalent iso-osmotic infusions. Frequently, such concentrated solutions appear to impose so severe a strain on the circulatory mechanism that the injection causes sudden death. In the controversy on the relative merits of concentrated and iso-osmotic protein solutions, the attention has been focused upon the proteins. Both proteins and total fluid volume are important. We are now studying the relative effect of volume-equivalent concentrated and iso-osmotic solutions. We have reason to believe that two or three times concentrated protein solutions given with sufficient fluid volume will prove the most effective form of therapy.

Summary

In conclusion, we may summarize by stating that:

1. Human serum and plasma are physiologically equal and physiologically active in combating conditions characterized by a depletion of plasma volume.

2. Liquid, frozen, or dried plasma have certain individual advantages based purely on the circumstances under which they will be used.

3. Plasma is a biologic and must be prepared with scrupulous care and proper safeguards and tests for safety.

4. The dosage required is usually large and should be adequate for restoration.

5. Repeated plasma injections may be required to maintain a normal plasma volume.

6. Fluid reserves and total fluid volume replacement are of great importance.

Preparation requires	Skilled care (a crude product more readily prepared)	Skilled care (a crude product more readily prepared)	Skilled care
Special preparation	None	The liquid plasma is frozen in a low-temperature refrigerator	The liquid plasma is dried with special machines
Storage	Refrigerator or room*	Special low-temperature refrigerator (−4 F.)	Room
Stability	Fibrin deposits in refrigerator	Good	Good
Expiration date	1 year	3 years	5 years
Special handling for administration	None	Thaw at 37 C.	Add distilled water and dissolve
Time required	.....	30 minutes	5 minutes or longer
Administration	For all forms, the intravenous outfit must be clean, sterile, and pyrogen-free		
Type of filter needed	Stainless steel mesh	Glass tape or stainless steel mesh	Glass tape or stainless steel mesh

* Liquid plasma is best stored at room temperature (60 to 85 F.) to minimize fibrinogen precipitation, although at these temperatures the antibodies are lost.

anoxemia, hemoconcentration, tissue anoxia, acidosis, and eventually death. Blood transfusion is effective. Plasma is effective. Any suitable macromolecular solution will restore and maintain the circulating plasma volume. Plasma is the most natural solution of this kind. Many others (pectin, gelatin) are still experimental.[4]

5. *Burns.*—This is one condition in which plasma loss is an outstanding feature and in which much plasma loss is a major cause of early shock and death. Plasma replacement is absolutely essential.

6. *Preoperative Therapy.*—It is well established that an important controlling factor in resistance to shock is blood protein and fluid reserves. Preoperative blood transfusions occupy an accepted place in any surgical routine. Plasma may well be substituted and will prove an invaluable preoperative measure to increase reserve stores of protein and fluid, and thereby decrease the operative risk. Blood transfusion is probably superior for this purpose, but difficulty of various kinds may attend the use of blood, and plasma can be readily available under any circumstance.

7. *Miscellaneous.*—Hypoproteinemia associated with malnutrition, nephrosis, or postoperative cachexia can be benefited by plasma therapy.

Blood transfusion has long been employed, empirically, for treatment of acute infections. When such infections are accompanied by secondary anemia, the erythrocytes are of value. Otherwise it is the proteins and particularly the antibodies in the adult serum or plasma which are beneficial. It is well known that adult serum, particularly from urban dwellers, contains antibodies against a variety of infections of known or unknown etiology.[5,6,7,8,9,10,11,12] Although this subject is at present largely unexplored, it is not impractical to consider the administration of pooled adult plasma in the treatment of common acute infections for which no specific therapy exists. This does not mean that indiscriminate treatment is advisable—quite the contrary. Until adequate studies have been made, plasma should be used circumspectly and critically for acute infections.

Dosage

This aspect of plasma therapy must be given the gravest consideration, because of a general misconception of what constitutes a proper dose. The common unit of plasma is 250 cc. or 300 cc., because this is the amount secured from a pint of blood, the standard amount withdrawn from a donor at venesection. Obviously this does not establish the proper unit for therapy. The dose depends upon the condition and the severity of the condition. In general, the dose to be administered is established by the quantity of blood or plasma that has been lost. This may be estimated by blood volume, erythrocyte, hemoglobin, and hematocrit determinations. In actual practice the principle guide to dosage is the clinical response of the patient. In severe or critical conditions, plasma should be given promptly, rapidly, and repeatedly until all evidence of shock or of oligemia has been overcome. Inadequate plasma therapy is wasted plasma. The response of the patient to treatment depends not only on the extent of injury but also on the length of time that shock has existed before therapy was instituted. The earlier treatment is instituted, the more rapid the response. If a condition is serious enough to require plasma, the absolute minimum to produce a response is 500 cc. More commonly

1,000 cc. are required, and in severe conditions and grave shock, 3,000 to 5,000 cc. may be necessary in the first twenty-four hours after injury.

It is important to realize that continued plasma therapy is often necessary to maintain the blood volume at normal levels because of continued plasma loss for one reason or another. The patient's condition, pulse, blood pressure, and the laboratory determinations are the best guide for plasma requirements. The patient must, therefore, be closely observed for at least seventy-two hours after onset for signs of recurrent shock.

These essentials of massive and repeated plasma therapy are particularly applicable to severe burns, where the plasma loss may be tremendous. In the past it was felt that the extensive plasma loss in burns required equally large plasma replacement, and various formulas[13,14,15] of estimating the dose were proposed. Some of these formulas were complicated, others inaccurate and usually too low, approximately 500 cc. for 10 per cent body burn. Both animal experiments[16,17,18] and clinical studies[13,14,19] demonstrate that plasma loss is usually in excess of the amount. In our own studies [19,20] in patients, based principally on the plasma requirements to re-establish and maintain normal conditions and values, we found it necessary to give larger amounts. Our course of plasma therapy consists of the following, based upon 10 per cent body burn: immediate infusion of 600 cc.; additional 300 cc. during the first twenty-four hours; a further 300 cc. in the next forty-eight hours. Continued plasma therapy may be required. The foregoing is only a working formula and is varied (usually increased), particularly in severe and extensive burns.

In considering the value of plasma as a restorative agent and concentrating on its protein content, one should not become oblivious to its water component. When plasma is lost in shock, water as well as protein is lost. If body reserves permit, water can very rapidly be drawn into the circulation. If the individual, however, is dehydrated, and fluid stores depleted, it is equally important to replace water as well as to restore proteins in order that the already dehydrated tissues be spared injury from further dehydration.

Studies in our laboratory with various macromolecular therapeutic agents clearly demonstrate that in shock, under any condition, the total fluid volume of the infused agent is of great importance.[21,22,23,24,25] Concentrated solutions are completely effective only if given with sufficient fluid. This is most strikingly demonstrated in animals in a dehydrated state. In the presence of severe dehydration, four times concentrated protein solutions administered in small volume of fluid are followed by a response which is much less prompt and rarely as complete as is seen after administration of protein equivalent iso-osmotic infusions. Frequently, such concentrated solutions appear to impose so severe a strain on the circulatory mechanism that the injection causes sudden death. In the controversy on the relative merits of concentrated and iso-osmotic protein solutions, the attention has been focused upon the proteins. Both proteins and total fluid volume are important. We are now studying the relative effect of volume-equivalent concentrated and iso-osmotic solutions. We have reason to believe that two or three times concentrated protein solutions given with sufficient fluid volume will prove the most effective form of therapy.

Summary

In conclusion, we may summarize by stating that:

1. Human serum and plasma are physiologically equal and physiologically active in combating conditions characterized by a depletion of plasma volume.

2. Liquid, frozen, or dried plasma have certain individual advantages based purely on the circumstances under which they will be used.

3. Plasma is a biologic and must be prepared with scrupulous care and proper safeguards and tests for safety.

4. The dosage required is usually large and should be adequate for restoration.

5. Repeated plasma injections may be required to maintain a normal plasma volume.

6. Fluid reserves and total fluid volume replacement are of great importance.

BILATERAL BLINDNESS DUE TO LESIONS IN BOTH OCCIPITAL LOBES

Report of Six Cases, Four with Necropsy

HENRY ALSOP RILEY, M.D., New York City,* JOSEPH C. YASKIN, M.D., M. E. RIGGS, M.D., and A. S. TORNEY, M.D., Philadelphia

THE localization of cerebral lesions is usually relatively easy if evident disturbances of unilateral cerebral functions can be demonstrated. This is true not only for destructive but also for irritative lesions. If a group of symptoms that are dependent upon a single pathologic focus is present, the diagnosis can usually be made by a careful consideration of the train of symptoms and a proper evaluation of the evidence elicited by a thorough examination of the patient, amplified by adequate laboratory procedures. Multiple foci of involvement, either inflammatory, vascular, degenerative, or neoplastic in character, greatly increase the difficulty in localization. Since it is more common to find single rather than multiple lesions, the tendency is to try constantly to explain the symptomatic evidence on the basis of a single lesion and only the presence of irreconcilable facts will justify the conclusion that multiple foci are producing the various indications of disturbed cerebral function. It is usually much more difficult to explain a number of symptoms on the basis of a single lesion; making the diagnosis of multiple lesions exposes the physician to the charge of diagnostic laziness. As a result, the diagnostician endeavors to unravel the symptomatic picture on the basis of a single lesion, ascribing evidences incompatible with the presence of a single lesion to diaschisis, displacement, or distortion. Only when one is driven to the conclusion that the underlying pathologic cause is capable of producing symptoms indicative of multiple involvement is the guess hazarded that a multiple cause is responsible for nonconcordant evidence. Inflammatory and metastatic pathologic processes often produce the picture of widespread multiple involvements. A single progressively expanding lesion arising in or near the midline frequently results in symptoms indicative of bilateral involvement of adjacent structures. The march of events clearly indicates the successive involvement of one function after another and the general symptoms often make perfectly clear the character of the pathologic process. Vascular accidents that occur serially frequently result in multiple lesions, but it is difficult to remember that symmetric simultaneous involvement of bilateral structures may be due to vascular disease.

Disturbances of vision are frequently of great value in the differential diagnosis of cerebral lesions. Characteristic types of visual loss are often of great assistance in making a localizing diagnosis. The pathway of the visual fibers from the retina to the calcarine cortex is definitely established, and only minutiae in regard to the course of the fibers are still under discussion. A knowledge of the anatomic relations of the various parts of the visual pathway is absolutely essential in the determination of the location of any lesion that interferes with the visual function.

Satisfactory vision depends upon the maintenance in a reasonably normal condition of the structures subserving the visual function. This includes the cornea, lens, media, retina, choroid, and the vessels of the retina before one even begins to consider the neural pathways and their complicated course. The transmissive and receptive apparatus must be in satisfactory functioning condition before one can even consider the neural constituents of the visual pathway in coming to any conclusion concerning the locus of factors that interfere with vision. Disturbances in the cornea, the various media, and the retina are frequent causes for bilateral diminution or loss of vision. The diagnosis of such conditions depends upon careful ophthalmoscopic examination. As soon as one passes beyond the parts of the visual apparatus which can be seen and objectively examined, one is in the realm of deduction and theoretic differentiation. It is under these circumstances that a knowledge of the rather intricate course of the visual pathway is indispensable to correct neurologic diagnosis.

Each eye presents a field of vision divisible into a number of parts—the temporal, nasal, upper, and lower fields of vision and macular vision. The mechanics of the media cause the portions of the retina corresponding to the various subdivisions of the visual field to be reversed. The upper and lower visual fields are served by the inferior and superior portions of the retina, respectively, while the temporal and nasal visual fields are served by the nasal and temporal portions of the retina, respectively. The macular field is the region of most acute visual

DOCTORS AND NURSES IN CHINA GROW PLANTS FOR NEEDED DRUGS

Doctors and nurses in China's vast northwest territory, surrounded on three sides by Japanese armies, have been forced by necessity to become farmers.

Because of a crucial shortage of drugs such as belladonna, digitalis, codeine, and morphine, Chinese physicians and surgeons looking after ill and wounded guerrilla soldiers are now attempting to cultivate plants producing the drugs. China Aid Council, a participating agency of United China Relief, announces that Mme. Sun Yat-sen, who sponsors medical aid to guerrilla fighters and their children in the northwest, has cabled an urgent appeal for information on the cultivation of the purple foxglove, whose leaves provide digitalis, and on the cultivation of the deadly nightshade plant, whose leaves produce belladonna.

Mme. Sun, who is the widow of the founder of the Chinese Republic, writes that codeine and morphine, so necessary on the battlefront, are now being extracted in small quantities from opium.

Blockaded on three sides by Japanese armies, this northwest area had not received outside medical aid for two years until recently, when several truckloads of medical supplies were sent through from Free China. In the past five and a half years, medical treatment of the thousands of Chinese guerrilla soldiers was made possible almost entirely by drugs and medicines captured from the Japanese or smuggled out from Peiping, and by the small quantities of drugs and serums manufactured in the local drug factory.

Mme. Sun writes that thousands of guerrilla soldiers have died, and many more have suffered unnecessarily for want of medicines in the northwest region, where fighting has been constant since Japan started her invasion in 1937. The death last December of Dr. Kotnis, a young doctor from India, director of the International Peace Hospital in Wutaishan, is said to have resulted from inadequate medical treatment due to drug shortage.

His predecessor, the Canadian, Dr. Norman Bethune, founder of the International Peace Hospitals, died in 1939 as a result of lack of drugs needed to treat an infection.

A drug factory and serum institute, aided by funds sent by China Aid Council of United China Relief, are now producing medicines made from local herbs and indigenous materials. Mme. Sun also writes that the low grade vaseline obtained from local oil fields is being improved upon by Chinese research chemists working in the drug factory.—*Connecticut State M. J.*

CHEMICAL TESTS GANGRENE

Lives threatened by gas gangrene infection in war wounds may be saved if a new chemical test proves as successful in the hands of military surgeons as it has in laboratory experiments.

The test depends on detecting in fluid excluded from the wound the presence of enzymes or ferments produced by the germs that cause gas gangrene.

The test was developed by Dr. D. McLean and Dr. H. J. Rogers, of England's Lister Institute of Preventive Medicine, and Dr. B. W. Williams, of St. Thomas's Hospital, London.

Gas gangrene develops so quickly that death may follow within a few hours and even experienced surgeons may have difficulty in making the diagnosis in time for effective treatment. Nor is the bacteriologist able to give him much help.

The new chemical test gives results within an hour and is simple to perform. By using an ordinary white-blood-cell-counting pipette with a few simple precautions it can, the scientists state, be carried out under field conditions.

So far it has been used only in laboratory experiments so that its practical value is not yet known. The scientists who developed it have published their results quickly so that it can be given an early trial in actual practice.

Of the enzymes produced by the gas gangrene germs, one, called hyaluronidase, is also produced by certain other germs. The scientists apparently believe, however, that it would be more practical to test for this enzyme as a diagnostic measure than for lecithinase, the presence of which would give a more specific diagnosis but which is likely to be present in only very small amounts at a time when detection of it would help the diagnosis.—*Science News Letter*

BILATERAL BLINDNESS DUE TO LESIONS IN BOTH OCCIPITAL LOBES

Report of Six Cases, Four with Necropsy

HENRY ALSOP RILEY, M.D., New York City,* JOSEPH C. YASKIN, M.D., M. E. RIGGS, M.D., and A. S. TORNEY, M.D., Philadelphia

THE localization of cerebral lesions is usually relatively easy if evident disturbances of unilateral cerebral functions can be demonstrated. This is true not only for destructive but also for irritative lesions. If a group of symptoms that are dependent upon a single pathologic focus is present, the diagnosis can usually be made by a careful consideration of the train of symptoms and a proper evaluation of the evidence elicited by a thorough examination of the patient, amplified by adequate laboratory procedures. Multiple foci of involvement, either inflammatory, vascular, degenerative, or neoplastic in character, greatly increase the difficulty in localization. Since it is more common to find single rather than multiple lesions, the tendency is to try constantly to explain the symptomatic evidence on the basis of a single lesion and only the presence of irreconcilable facts will justify the conclusion that multiple foci are producing the various indications of disturbed cerebral function. It is usually much more difficult to explain a number of symptoms on the basis of a single lesion; making the diagnosis of multiple lesions exposes the physician to the charge of diagnostic laziness. As a result, the diagnostician endeavors to unravel the symptomatic picture on the basis of a single lesion, ascribing evidences incompatible with the presence of a single lesion to diaschisis, displacement, or distortion. Only when one is driven to the conclusion that the underlying pathologic cause is capable of producing symptoms indicative of multiple involvement is the guess hazarded that a multiple cause is responsible for nonconcordant evidence. Inflammatory and metastatic pathologic processes often produce the picture of widespread multiple involvements. A single progressively expanding lesion arising in or near the midline frequently results in symptoms indicative of bilateral involvement of adjacent structures. The march of events clearly indicates the successive involvement of one function after another and the general symptoms often make perfectly clear the character of the pathologic process. Vascular accidents that occur serially frequently result in multiple lesions, but it is difficult to remember that symmetric simultaneous involvement of bilateral structures may be due to vascular disease.

Disturbances of vision are frequently of great value in the differential diagnosis of cerebral lesions. Characteristic types of visual loss are often of great assistance in making a localizing diagnosis. The pathway of the visual fibers from the retina to the calcarine cortex is definitely established, and only minutiae in regard to the course of the fibers are still under discussion. A knowledge of the anatomic relations of the various parts of the visual pathway is absolutely essential in the determination of the location of any lesion that interferes with the visual function.

Satisfactory vision depends upon the maintenance in a reasonably normal condition of the structures subserving the visual function. This includes the cornea, lens, media, retina, choroid, and the vessels of the retina before one even begins to consider the neural pathways and their complicated course. The transmissive and receptive apparatus must be in satisfactory functioning condition before one can even consider the neural constituents of the visual pathway in coming to any conclusion concerning the locus of factors that interfere with vision. Disturbances in the cornea, the various media, and the retina are frequent causes for bilateral diminution or loss of vision. The diagnosis of such conditions depends upon careful ophthalmoscopic examination. As soon as one passes beyond the parts of the visual apparatus which can be seen and objectively examined, one is in the realm of deduction and theoretic differentiation. It is under these circumstances that a knowledge of the rather intricate course of the visual pathway is indispensable to correct neurologic diagnosis.

Each eye presents a field of vision divisible into a number of parts—the temporal, nasal, upper, and lower fields of vision and macular vision. The mechanics of the media cause the portions of the retina corresponding to the various subdivisions of the visual field to be reversed. The upper and lower visual fields are served by the inferior and superior portions of the retina, respectively, while the temporal and nasal visual fields are served by the nasal and temporal portions of the retina, respectively. The macular field is the region of most acute visual

* From the Neurological Institute of New York.

function and is represented in both occipital lobes. In the optic nerve are combined all the fibers of vision from the entire retina of each eye alone, the fibers from the various upper, lower, temporal, and nasal regions of the retina retaining their position in correspondence to the point of origin of the various fibers, central vision remaining centrally located in the optic nerve. At the optic chiasm, the visual fibers undergo a process of rearrangement; the nasal retinal fibers serving temporal vision undergo a decussation and become crossed in the median portion of the chiasm, whereas the fibers from the temporal retinal cells serving nasal vision proceed caudally without changing sides. In the optic nerve and chiasm, the fibers from the upper retinal region remain dorsally located, whereas the lower retinal elements remain ventral. The macular fibers consist of both crossed and uncrossed elements. Behind the chiasm, the fibers become reassorted so that now each optic tract consists of fibers from each eye; in each tract the homolateral temporal retinal elements are joined by elements arising from the contralateral nasal retinal regions, with macular elements from both sides. This rearrangement results in a visual function of gaze to either one side or the other, contributed to by both eyes cooperating with each other, the left eye looking to the right by means of its temporal retinal elements, the right eye to the right through its nasal retinal elements and vice versa. The upper and lower half quadrants of nasal and temporal vision retain in the optic tract the upper and lower position which they occupied in the optic nerve and chiasm corresponding to their derivation from the upper and lower homolateral and contralateral portions of the retinae. The optic tract also contains coarse fibers which arise from all parts of the retina and are concerned with the transmission of stimuli occasioned by the relative amount of illumination. The optic tract terminates principally in the lateral geniculate body of the homolateral metathalamus. At this point a separation of light from sight fibers takes place, the light fibers passing to the superior colliculus and thence to the homolateral oculomotor nucleus and the contralateral colliculus and oculomotor nucleus for the purpose of completing the reflex arcs that are responsible for the direct and consensual pupillary reflexes. Caudal to the lateral geniculate body the visual radiation carries the visual stimuli to the calcarine cortex, which forms the lips of the calcarine fissure. The ventral lip of the calcarine fissure is continued cephalically as the cortex of the lower margin of the anterior calcarine fissure to its termination on the hippocampal gyrus. The arrangement of the fibers in the visual or calcarine radiation remains much the same as that which exists in the optic tract, the fibers derived from the upper quadrant of the homolateral temporal retinal area and the upper quadrant of the contralateral nasal retinal area ending in the upper lip of the calcarine fissure and vice versa. Outside of this arrival platform level in the calcarine area are secondary and tertiary areas which are concerned with the associational activities of the visual cortex and carry on first the perceptual functions of the visual cortex with the recognition of objects as such and the still higher associational values of nominal appreciation and fusion with other cortical associational functions.

Lesions affecting the visual apparatus produce interferences with vision in accordance with the anatomic location of the lesion and the pattern of the visual pathways at the actual point of involvement. The resulting loss of vision also depends upon the completeness of the involvement of the structures that are affected. Disturbances of any subdivision of the visual function may be complete or incomplete, but any such subtotal disturbance will still present the anatomic characteristics dependent upon the actual anatomic relations belonging to the particular part of the apparatus involved.

Without going into the ultimate minutiae of anatomic subdivisions, lesions of the lens, media, or coats of the eyeball and of each optic nerve produce disturbances in the total vision of each eye. In the chiasm, lesions of the central part of the chiasm produce a loss of vision to each temporal side since the crossing fibers from each nasal retinal region, serving vision to each side, are involved, which results in the so-called bitemporal hemianopsia. A lesion of one side of the chiasm such as might result from the pressure of an aneurysm of the internal carotid artery, will produce a loss of nasal vision in the affected eye (Fig. 1). If the lateral chiasmal lesion is bilateral, a binasal hemianopsia will result. A lesion that involves the optic tract between the chiasm and the lateral geniculate body will result in a homonymous hemianopsia, affecting vision either to the left or right and producing half-eyed blindness in each eye. If the lesion is in the right tract, the result will be a left homonymous hemianopsia, affecting the homolateral temporal retina and producing nasal field blindness while the contralateral nasal retina produces a temporal field blindness, thus destroying all vision to the left and vice versa. The pupillary reflex arising from illumination of the blind halves of the retina will also be lost. If the lesion affects the visual radiation behind the lateral geniculate body, involving the radiation or the calcarine area, the result will be almost the same, produc-

ng a homonymous hemianopsia to the opposite side, but the light reflex from the blind field will be retained since these light fibers have been diverted from the optic pathway to the superior colliculus in front of the location of the lesion and, therefore, are not involved by the lesion. Lesions limited to the upper or lower portion of the chiasm, tract, geniculate body, visual radiation, and calcarine cortex uniformly present disturbances in the upper or lower portion of the associated nasal and temporal fields of the two eyes. Lesions in the associational cortex produce the various visual agnosias, the results of the destruction of the association, correlation, and memory functions of the cortex. The individual may still be able to see objects, but he no longer recognizes the character and significance of visual representations.

Bilateral blindness under usual conditions is the result of bilateral lesions of the mediae, retina, or optic nerves of the two eyes. Neurologic causes for bilateral blindness are bilateral severe retinitis, papilledema, optic neuritis, or bilateral optic nerve atrophy, the result of toxic or infectious processes, bilateral pressure of sphenoidal ridge neoplasms on, or traumatic separation of, the two optic nerves or the entire chiasm, the result of fracture through the floor of the cephalic portion of the middle fossa of the skull, or penetrating wounds.

In the region between the caudolateral angles of the chiasm and the calcarine areas it is almost impossible to produce bilateral blindness because of the fact that the two optic tracts and radiations are widely separated from one another. The two visual radiations, however, gradually approach each other as they proceed caudally, and finally in the calcarine region they are only about 5 mm. apart, separated from each other by the falx just before its incorporation into the tentorium.

The two calcarine areas are almost in contact with each other and are thus vulnerable to midline lesions that occur in that part of the falx, such as a meningioma. A tumor arising in one calcarine area may expand across the midline and progressively involve the other calcarine area until the function of each visual area is destroyed.

Bilateral blindness from crushing injuries of the occipital regions of the skull and from penetrating wounds of the skull occurs with considerable frequency both in civilian accidents and under conditions of warfare. The condition under these circumstances is readily recognized, and the diagnosis can be made without any difficulty. Blindness from progressive subcortical encephalopathy with demyelinization (Schilder's disease) and from extremely severe wide-

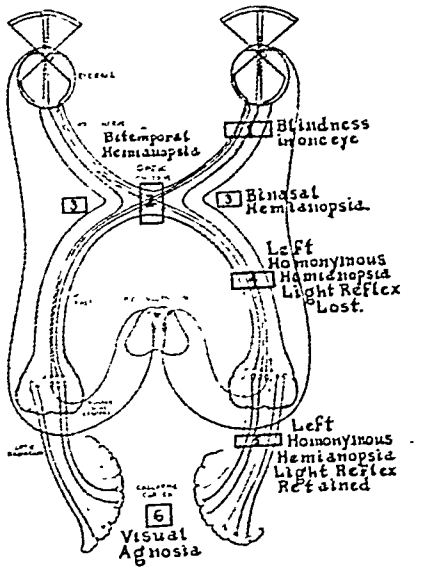

FIG. 1. Diagram of the visual pathway showing the location of lesions which result in disturbances of vision.

spread cortical or subcortical intoxication (carbon monoxide poisoning) is not infrequently encountered, but the circumstances attending the onset and the associated phenomena usually render the diagnosis reasonably easy.

Finally, vascular conditions may result in bilateral involvement of the occipital areas. The major blood supply of the occipital lobes, especially the calcarine areas, is provided by each posterior cerebral artery. Occasionally the anterior cerebral artery may extend far enough caudally in the interhemispheric fissure to contribute to the blood supply of the calcarine areas and rather more frequently some blood supply for this area may be derived from the terminal cortical branches of the middle cerebral artery, but the posterior cerebral arteries produced by the bifurcation of the basilar artery are the main source for the blood supply of the visual cortices.

Certain arteriosclerotic processes seem to present a predilection to involve the vertebral, basilar, and posterior cerebral group of vessels and when this process results in a serious interference with the transmission of blood, bilateral softening of the occipital lobes may result in total blindness.

Von Monakow[1] in 1914 reported 20 cases of total blindness due to bilateral occipital lobe lesions, either from vascular or infiltrating processes. In many of these cases the disturbance first appeared as a hemiopic defect, followed by complete

blindness as a result of involvement of the remaining hemiopic field by the pathologic process. Bramwell[2] and his coauthors in 1915 reported a case of blindness from bilateral lesions of the occipital lobes with retention of macular vision as distinct from panoramic vision. Mella[3] in 1922 reported a case of thrombotic cortical amaurosis, the result of the action of wood alcohol. Marquis[4] in 1932 in reviewing the literature reported 9 patients completely and permanently blind, 6 of these cases being caused by vascular lesions and three being the result of trauma. Two cases were reported by Hemphill[5] in 1941 as results of occlusion of the basilar artery.

The relative infrequency of bilateral blindness due to vascular or neoplastic lesions in both occipital lobes prompted the authors to report these 6 cases—4 with necropsy evidence, one with preservation of central vision, and one showing how the preliminary phase of a situation might have eventuated in total blindness, had it continued its logical course.

Case Reports

Case 1.—Summary: A 64-year-old woman developed, following the death of her husband, a variety of complaints which were regarded as neurotic. In the course of nine weeks she gradually developed complete blindness, first in the left eye and then in the right eye. A study of the fundi disclosed no cause for the blindness. In the course of a few weeks she developed a right facial palsy, pyramidal tract signs, some increase in intraspinal pressure, a metastatic nodule in the neck, and x-ray evidence of carcinoma of the stomach.

History: S. B., aged 64, with an irrelevant family history, a surgical menopause at the age of 23, *widowed in 1937, was first examined on June 7, 1939,* and gave the following historical data: She stated that she took the death of her husband seriously but got along fairly well until about one year before, when she developed marked vertigo, fatigue, anorexia, a coated tongue, drowsiness, and loss of about 10 pounds in weight. This condition continued from May until September, 1938, when she improved and regained the 10 pounds that she had lost. About six weeks before the examination she began to lose sight in the left eye. This, she insisted, was gradual. Accompanying this symptom were loss of appetite, bitter taste in the mouth, fatigability, a feeling of fullness in her feet, pain in the right leg, and some difficulty in sleeping. She stated that in the course of from three to four weeks she lost the sight in her left eye and about two weeks before began to lose the sight in her right eye. About two weeks before she had an attack of dizziness and again another severe attack two days before. She stated that she experienced minor attacks of dizziness off and on. Her chief difficulties are failure in vision of both eyes, anorexia, vertigo, fatigability, and a general feeling of ill-being.

Examination: Weight: 100½ pounds; pulse: 72; blood pressure: 160/70. The examination of the skin and lymphatic system was negative. All the teeth had been removed. The tongue was clean, moist, and did not show any atrophy. The thyroid gland was not enlarged. The heart was moderately enlarged, and there were no murmurs. The liver and spleen were not palpable.

Mentally, the patient showed no gross deviations in the intellectual sphere. Her memory, orientation, and general grasp of knowledge were all quite within normal limits. She continued to repeat herself regarding her difficulties—the fact that every part of her body was dying, that she did not eat for days at a time, etc. The complaints were unaccompanied by any corresponding degree of anxiety. She dwelt at length on the qualities of her husband and on the fact that she had had a very definite social position, which she lost at his death.

Hospital observations: The patient was first admitted to the Graduate Hospital in May, 1939, when a diagnosis of retinal angiosclerosis was made and the absence of free hydrochloric acid was found in the gastric analysis. She was readmitted to the Graduate Hospital on June 21, 1939, and discharged on August 5, 1939. Her temperature was normal, but her pulse during the first two weeks of hospitalization was 60 per minute and less.

She was examined by four ophthalmologists who failed to find any cause for her blindness, which was complete. The pupils were somewhat dilated and responded poorly to light. There were bilateral nuclear cataracts.

Urinalysis, blood count, blood Wassermann, blood sugar, and blood urea nitrogen values were normal. The spinal fluid pressure was 200 mm. of water, and a detailed examination of the spinal fluid was negative. X-ray study of the skull was negative. The x-ray of the chest on June 24, 1939, revealed a moderately sclerotic and dilated aorta with increased truncal markings associated with pleural thickening in the right lung field. In addition there was a nodular opacity in the right upper lung. A re-examination of the chest on July 21, 1939, showed no alterations from those previously noted and the lung changes were regarded as inflammatory and not metastatic. X-ray examination of the long bones showed no evidence of metastases. The Bárány examination suggested the presence of a midline supratentorial lesion.

The patient continued to complain of anorexia, general weakness, and pain in various parts of her body. On July 20, 1939, there were observed a small, hard, partially movable nodule in the right supraclavicular region, a definite right central facial palsy, and a right-sided Babinski sign. Biopsy of this nodule disclosed a scirrhus carcinoma. The x-ray of the stomach revealed a filling defect and an irregularity in the cardiac portion of the stomach, neoplastic in nature.

The patient died at home several weeks after discharge from the hospital, and no necropsy was obtained.

Comment: It is reasonable to assume that this patient had bilateral occipital lobe metastatic carcinoma. This diagnosis is supported by the gradual

onset of the symptoms and the completeness of the blindness, contrasting with the relatively mild pyramidal tract involvement. The personality makeup of the individual and the psychoneurotic reaction masked the slowly developing neoplasms, the more so because the evidences of increased intracranial pressure, especially headache, were slight.

Case 2.—Summary: A 49-year-old white man was admitted several times to the Philadelphia General Hospital, the last two admissions being for a progressive type of neurologic disorder, apparently not limited to one part of the brain, so that a diagnosis of multiple cerebral vascular lesions was made. During his last admission it was noted that the patient had only central vision intact. He died suddenly. The necropsy revealed a softening in both occipital lobes in the course of the posterior cerebral arteries. The tips of both occipital lobes were intact.

History: W. G. (26-155), a 49-year-old white man, had three hospitalizations at the Philadelphia General Hospital in 1920, 1925, and 1926. His history stated that in August, 1918, he had had diplopia which disappeared. In August, 1920, he had been "tongue-tied" for three weeks, but this, too had cleared up. He was admitted to the Philadelphia General Hospital in September, 1920, complaining of severe pain in his right hip radiating down his right leg to his toes. The pain was worse at night. At this time it was noted that his intelligence was markedly impaired; there was a slight dysarthria, impaired vision in the temporal field of the right eye and the nasal field of the left eye, loss of upward rotation of his eyes, and loss of convergence of the right eye. All the tendon reflexes were overactive with bilateral patellar clonus and a questionably positive bilateral Babinski sign. The tongue protruded to the right, and sensation was diminished on the posterior one-third of the tongue. There was an anesthesia of the uvula and left half of the palate. He had an ataxic tremor of the right hand and a positive Romberg sign. The spinal fluid revealed 4 cells and a negative Wassermann reaction. The patient remained at the hospital four years before he was discharged. He was readmitted on the service of Dr. J. W. McConnell on December 21, 1925. Unfortunately, the part of the history dealing with the interval between his discharge from the hospital and his readmission in December, 1925, and the complaints of the patient on readmission in December, 1926, could not be obtained.

Examination: Study of the patient revealed a poorly nourished white man, with evidence of pneumonia at the base of the right lung. He also had evidence of myocardial change as shown by heart sounds of poor quality and roughening of the first sound at the apex. His gait was uncertain, spastic, with some shuffling, and there was a positive Romberg sign. There was no ataxia. There was some exophthalmus of the left eye; the pupils were irregular and eccentric, reacting very slightly to light and sluggishly upon accommodation. There was blindness in both temporal visual fields, and the patient could not see objects more than a few feet in front of him. Although all the ocular movements were retained, convergence was not well done. His speech was slow, jerky, and monotonous. All the tendon reflexes were increased. There was no disturbance of sensation.

Ophthalmologic examination by Dr. Percy De Long: Eye rotations full, no paralysis; pupils irregular and unequal reacting to light and upon accommodation; disks well defined and healthy; blood vessels normal for age; no hemorrhages or exudates. Perimetric examination showed the fields of both eyes to be contracted, with only central vision intact.

The Bárány tests were reported by Dr. Hunter to be normal.

Laboratory studies: March 29, 1925—red blood cells, 4,288,000; white blood cells, 15,800; March 16, 1926—red blood cells, 3,430,000; white blood cells, 9,300. A blood Wassermann reaction was negative. The blood urea nitrogen was 27 mm. per cent; the blood sugar was 11 mm. per cent. A spinal fluid examination revealed no cells and a negative Wassermann reaction.

An x-ray of the patient's chest showed fibrosis in the upper lobe of the right lung and discrete shadows in the left apex, indicating pulmonary tuberculosis. An x-ray of his skull revealed a normal sella turcica.

Course in hospital: The patient slowly lost ground and frequently refused to eat. During his hospital stay he developed signs of cavitation in both apices. Two weeks prior to his death, a drooping of the right side of the face and narrowing of the right palpebral fissure were noted; voluntary facial movements were decreased on the right side; deviation of the tongue to the right took place on protrusion; there was decreased power in the right extremities; and the reflexes in the right extremities were increased. There was a dysphasia, which seemed to be due to a dysarthria, and marked mental deterioration, especially for past events, developed. The patient died suddenly one day on getting out of bed.

Necropsy report: The brain was normal in size. The basilar vessels were fibrotic. On the inferior surface of the right occipital lobe there was a scar of an old vascular lesion. This involved the mesial third of the inferior surface and approximately the posterior half of the inferior mesial surface. The occipital pole appeared to be spared. On section the lesion extended to the ependymal wall of the occipital horn of the right hemisphere and became progressively less extensive above the roof of the occipital horn. The lesion involved the subcortical white matter to a greater extent through the overlying cortex. There was a similar lesion on the left side. Here, there was only a small area of cortical involvement on the inferior surface. The calcarine cortex appeared atrophic but not grossly degenerated. However, on section, the subcortical involvement on the inferior mesial surface was practically identical with that on the right hemisphere. Bilateral cortical lesions in the distribution of the superior cerebellar artery were noted in the cerebellar hemispheres.

Comment: This patient had preservation of central vision and anatomically a sparing of the occipi-

blindness as a result of involvement of the remaining hemiopic field by the pathologic process. Bramwell[2] and his coauthors in 1915 reported a case of blindness from bilateral lesions of the occipital lobes with retention of macular vision as distinct from panoramic vision. Mella[3] in 1922 reported a case of thrombotic cortical amaurosis, the result of the action of wood alcohol. Marquis[4] in 1932 in reviewing the literature reported 9 patients completely and permanently blind, 6 of these cases being caused by vascular lesions and three being the result of trauma. Two cases were reported by Hemphill[5] in 1941 as results of occlusion of the basilar artery.

The relative infrequency of bilateral blindness due to vascular or neoplastic lesions in both occipital lobes prompted the authors to report these 6 cases—4 with necropsy evidence, one with preservation of central vision, and one showing how the preliminary phase of a situation might have eventuated in total blindness, had it continued its logical course.

Case Reports

Case 1.—Summary: A 64-year-old woman developed, following the death of her husband, a variety of complaints which were regarded as neurotic. In the course of nine weeks she gradually developed complete blindness, first in the left eye and then in the right eye. A study of the fundi disclosed no cause for the blindness. In the course of a few weeks she developed a right facial palsy, pyramidal tract signs, some increase in intraspinal pressure, a metastatic nodule in the neck, and x-ray evidence of carcinoma of the stomach.

History: S. B., aged 64, with an irrelevant family history, a surgical menopause at the age of 23, widowed in 1937, was first examined on June 7, 1939, and gave the following historical data: She stated that she took the death of her husband seriously but got along fairly well until about one year before, when she developed marked vertigo, fatigue, anorexia, a coated tongue, drowsiness, and loss of about 10 pounds in weight. This condition continued from May until September, 1938, when she improved and regained the 10 pounds that she had lost. About six weeks before the examination she began to lose sight in the left eye. This, she insisted, was gradual. Accompanying this symptom were loss of appetite, bitter taste in the mouth, fatigability, a feeling of fullness in her feet, pain in the right leg, and some difficulty in sleeping. She stated that in the course of from three to four weeks she lost the sight in her left eye and about two weeks before began to lose the sight in her right eye. About two weeks before she had an attack of dizziness and again another severe attack two days before. She stated that she experienced minor attacks of dizziness off and on. Her chief difficulties are failure in vision of both eyes, anorexia, vertigo, fatigability, and a general feeling of ill-being.

Examination: Weight: 100½ pounds; pulse: 72; blood pressure: 160/70. The examination of the skin and lymphatic system was negative. All the teeth had been removed. The tongue was clean, moist, and did not show any atrophy. The thyroid gland was not enlarged. The heart was moderately enlarged, and there were no murmurs. The liver and spleen were not palpable.

Mentally, the patient showed no gross deviations in the intellectual sphere. Her memory, orientation, and general grasp of knowledge were all quite within normal limits. She continued to repeat herself regarding her difficulties—the fact that every part of her body was dying, that she did not eat for days at a time, etc. The complaints were unaccompanied by any corresponding degree of anxiety. She dwelt at length on the qualities of her husband and on the fact that she had had a very definite social position, which she lost at his death.

Hospital observations: The patient was first admitted to the Graduate Hospital in May, 1939, when a diagnosis of retinal angiosclerosis was made and the absence of free hydrochloric acid was found in the gastric analysis. She was readmitted to the Graduate Hospital on June 21, 1939, and discharged on August 5, 1939. Her temperature was normal, but her pulse during the first two weeks of hospitalization was 60 per minute and less.

She was examined by four ophthalmologists who failed to find any cause for her blindness, which was complete. The pupils were somewhat dilated and responded poorly to light. There were bilateral nuclear cataracts.

Urinalysis, blood count, blood Wassermann, blood sugar, and blood urea nitrogen values were normal. The spinal fluid pressure was 200 mm. of water, and a detailed examination of the spinal fluid was negative. X-ray study of the skull was negative. The x-ray of the chest on June 24, 1939, revealed a moderately sclerotic and dilated aorta with increased truncal markings associated with pleural thickening in the right lung field. In addition there was a nodular opacity in the right upper lung. A re-examination of the chest on July 21, 1939, showed no alterations from those previously noted and the lung changes were regarded as inflammatory and not metastatic. X-ray examination of the long bones showed no evidence of metastases. The Bárány examination suggested the presence of a midline supratentorial lesion.

The patient continued to complain of anorexia, general weakness, and pain in various parts of her body. On July 20, 1939, there were observed a small, hard, partially movable nodule in the right supraclavicular region, a definite right central facial palsy, and a right-sided Babinski sign. Biopsy of this nodule disclosed a scirrhus carcinoma. The x-ray of the stomach revealed a filling defect and an irregularity in the cardiac portion of the stomach, neoplastic in nature.

The patient died at home several weeks after discharge from the hospital, and no necropsy was obtained.

Comment: It is reasonable to assume that this patient had bilateral occipital lobe metastatic carcinoma. This diagnosis is supported by the gradual

basis of an extensive alcoholism. Subsequent to his first neurologic examination he experienced more severe attacks which finally resulted in complete blindness. He was operated upon and died.

History: W. C. B. (647668), aged 44, a salesman, was first seen on January 15, 1942. He was admitted to the Neurological Institute on January 19, 1942, and died on January 30, 1942. Complaints: (1) "blackouts," and (2) poor memory.

About 1931, while under the strain of driving an automobile at night the patient became dizzy. He was able to pull his car to the side of the road, left the car, and fell to the ground. He vomited and felt badly for some time, but no further recurrence took place until the onset of the present difficulty.

The presenting symptoms began in the summer of 1941 without previous illness, any particular strain, or accident. While playing bridge he suffered a sudden attack of divergence and rolling of his eyes and inability to talk. He kept yawning for about half an hour. When he began to talk, he mumbled. There was no headache, but he felt very drowsy and sleepy. He recovered completely by the next day.

Two weeks after the attack in 1941 he had another similar episode, and following this second attack these occurrences were repeated frequently. Two or three weeks might go by without an attack or he might have two or three mild episodes in the same day. He had four severe attacks consisting of blurring of vision, turning of objects counterclockwise, and inability to talk. During these periods, he dropped objects from his hands. The attacks might last five or more minutes, after which he felt sleepy. He yawned considerably, but there were no sequelae. In the minor spells his vision became blurry, and he had some dizziness. He usually shut his eyes, and after about five minutes the attack passed off. There seemed to be no particular periodicity, regularity, or exciting causes for the attacks, and they did not seem necessarily to be associated with undue fatigue, nor did they present any relation to his meals. However, they did seem to follow emotional disturbances.

About the first of December, 1941, he had an attack which his wife stated lasted for about thirty minutes, in which he staggered, groped as if he were blind and intoxicated, and could not talk. There was no disturbance of sphincteric control in any of the attacks. He knew what was going on, but he could not talk. He was inclined to be rather talkative after the attack. His memory, on which he formerly prided himself, had become quite poor. He had to apply himself to business matters, and found that he could not remember the names of his business associates.

For many years he had been a periodic drinker. He came from an alcoholic family. His alcoholic career had begun when he was 14 or 15 years old and had continued as periodic alcoholic excesses. These bouts had been separated by varying periods of time. He neglected his meals when he was drinking.

Except for his alcoholic history, and the fact that his mother died at 70 of a cerebral accident, there was nothing important in his past, family, or personal history. He had always been an erratic eater, eating very few potatoes or green vegetables. He smoked about one and one-half packages of cigarettes a day. He had had only one operation, a rectal one for a fistula.

Examination: The patient was rather overweight—173½ pounds—and presented a rather pudgy, pasty appearance. A mottled, erythematous eruption—not burning, itching, or scaling—was found on both hands and forearms, and to a lesser extent on his legs. His blood pressure was 120/70; his pulse rate was 90 per minute. The heart sounds were distant. The cardiac outline was normal on percussion. The radial artery was felt to be normal, but the dorsalis pedis arteries were difficult to palpate.

Neurologic examination: There was some tremulousness under emotional tension. The finger-to-thumb test was performed in a rather disorganized manner. The reflexes were rather underactive. The abdominal reactions were bilaterally present and weak plantar flexion was elicited. There were no sensory disturbances. The visual fields were grossly complete. The fundi showed no definite abnormalities. The pupils reacted normally and were equal, but convergence was poorly maintained.

On the morning of the examination the patient stated that he had been unable to read the paper that morning, but that his distant vision was satisfactory.

On January 17, the patient had several severe spells which were followed by temporary loss of vision and an accentuation of the memory disturbance. There were repeated attacks of confusion, but he did not lose consciousness. His vision continued to be quite variable. He was at times euphoric, and the memory disturbance increased rapidly. On January 18 there were two attacks of confusion and rolling of the eyes, with irregular movements of the extremities but without definite convulsions.

On account of the frequent recurrence of his attacks, the increase in his visual disturbances, and loss of memory, he was admitted to the Neurological Institute on January 19, 1942.

Laboratory studies: Blood count, hemoglobin 13.7 Gm. (94 per cent); red blood count, 4,880,000; white blood count, 14,200; smear, normal; polymorphonuclears, 78 per cent; lymphocytes, 18 per cent; mononuclears, 3 per cent; and eosinophils, 1 per cent. Blood chemistry—nonprotein nitrogen, 40 mg. per cent; sugar 99 mg. per cent. Plasma vitamin C = 0.1 mg. per cent. Sugar tolerance—fasting, 99 mg. per cent; one-half hour, 146 per cent; one hour, 152 per cent; two hours, 135 per cent; three hours, 95 per cent; four hours, 68 per cent. Kline test, negative. Urinalysis—specific gravity, 1.018; alkaline reaction; no albumin, glucose, or acetone; no red blood cells; occasional white blood cells; no casts. Spinal fluid—total protein 60 mg. per cent; very slightly yellow; total white blood cells, 2; colloidal gold, 1,100,000,000; Wassermann reaction, negative. Basal metabolism was −15 per cent. Spinal fluid (January 26, 1942)—total white blood count, 4; total protein, 67 mg. per cent.

tal poles. This case is of particular value in that it demonstrates that the posterior cerebral arteries are not the sole source of blood supply of the occipital poles.

Case 3.—Summary: A 51-year-old colored man gradually lost his vision in 1940. Three days prior to admission to the Philadelphia General Hospital he developed a left hemiplegia (February 16, 1942) accompanied by marked mental confusion. He never regained consciousness and died on the sixth day after hospitalization. A necropsy revealed bilateral old vascular lesions in the terminal distribution of the posterior cerebral and left superior cerebellar arteries.

History: C. S., a 51-year-old colored man was admitted to the Philadelphia General Hospital (Service of J. C. Y.) on February 19, 1942. Because of clouding of consciousness, it was difficult to obtain an accurate history from the patient. A note from the referring physician, Dr. J. W. Roberts, stated that the patient developed a left hemiplegia on February 16, 1942. The patient stated that he had been blind for two years. This was confirmed by his wife, who stated that he had gradually lost his vision. Through the courtesy of Dr. Spaeth, we are able to include the following information taken from the clinic records:

"First seen 10/12/40, complaining of poor vision. A high degree of arteriosclerotic retinal vascular pathology was found. He could only count fingers. On 10/16/40 an effort at refraction resulted in no improvement in his vision. He was last seen 10/19/40 when the diagnosis of hypertensive arteriosclerotic retinal disease was confirmed."

Examination: The skin and mucous membranes appeared normal. The apex beat of the heart was in the sixth interspace in the anterior axillary line. The heart was enlarged on percussion. There was a soft systolic apical murmur with accentuation of the second mitral sound. The blood pressure was 190/150. There was marked peripheral arteriosclerosis.

Neurologic examination: There was a left flaccid hemiplegia and a left hemihypesthesia. The patient was restless, thrashing about with his right arm and leg. Because of lack of cooperation, examination of sensation and coordination of the right side of the body could not be carried out. The ophthalmologic consultant, Dr. J. B. Rudolphy, reported as follows: "The patient's lateral rotations are full. I am unable to elicit upward and downward movements because of lack of cooperation. Both lenses show opacities, the left more than the right. The right disk is well defined, gives no evidence of neuritis or choking, is of good color, and shows no evidence of atrophy. The arteries are generally reduced in caliber and are tortuous. The left disk is well defined, but shows decreased capillarity compared with that of the right.

"Other than well advanced angiosclerosis, there is no definite pathology of the fundi."

There was some clouding of consciousness and mild confusion. The patient seemed to have some difficulty in speaking. He would not talk above a whisper.

Laboratory studies: Urinalysis revealed a trace of albumin and sugar with a negative microscopic examination. The blood urea nitrogen was 27 mg. per cent; the blood sugar was 96 mg. per cent. The blood Wassermann and Kline reactions were reported as being negative.

Course in hospital: The temperature, pulse, and respiration remained at approximately the same level throughout the patient's hospital stay. He complained of some headache. He died suddenly on the sixth day after admission.

Necropsy report: Aorta—advanced atherosclerosis. Heart—severe left ventricular hypertrophy. Kidney—arterio- and arteriolar sclerosis. Brain—chronic passive congestion. The circle of Willis presented severe occlusion and ulcerative arteritis. There was a recent anemic softening involving the right rolandic area and the postcentral convolution. In the occipital lobes there were bilateral symmetric cortical scars. These involved the mesial two-thirds of the occipital lobes in their caudal third. The greater portion of the cunei were involved on the mesial surface, although the immediate area around the calcarine cortices appeared to be grossly uninvolved. The occipital poles were preserved. The cortex in the involved area was firm, brownish, and atrophic. On section, the lesion appeared to involve only the cortex and subcortex; however, the white matter was unusually firm and rubbery. There was a similar vascular lesion involving the cortex of the tentorial surface of the left cerebellar hemisphere in the distribution of the superior cerebellar artery. The white matter of both occipital lobes showed an overgrowth of fiber-forming astrocytes. There was an associated loss of myelin tissue, the demyelinization being most intense in the central regions. There was a relative preservation of the subcortical fibers. The cortex showed many focal lesions of varying age and intensity. These varied from ischemic cellular degeneration of the second and third layers to complete tissue degeneration with mobilization of gitter cells. In some areas the cortical layers were obliterated by astrocytic proliferation. There were perivascular and subarachnoid collections of lymphocytes and plasma cells. The arteries supplying the occipital area showed atheroma with marked narrowing of the lumen. The optic nerve (retrobulbar portion) showed slight, patchy demyelinization. The pathologic changes in this case suggested a progressive circulatory insufficiency rather than a sudden complete occlusion of the main vessel. The round cell infiltration might be accounted for on the basis of reaction to degeneration.

Comment: This man was apparently completely blind. The pathologic changes were in the terminal branches of the vessels that supply the occipital lobes. Moreover, the severe changes in the circle of Willis seriously interfered with the blood supply even if some of the terminal branches had remained intact. Early in the course of his disease the visual impairment was ascribed to vascular changes in the fundi.

Case 4.—Summary: A 44-year-old salesman developed recurrent "blackouts" apparently on the

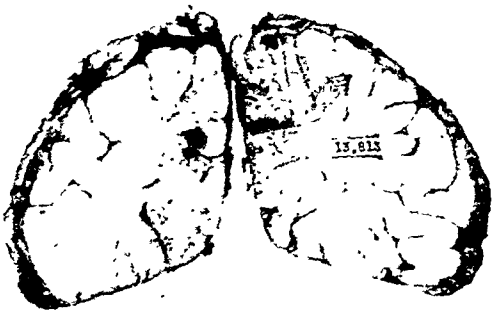

FIG. 3. W. B. Cross section of the occipital lobes showing bilateral old and recent hemorrhage and softening in the calcarine cortex and adjacent areas.

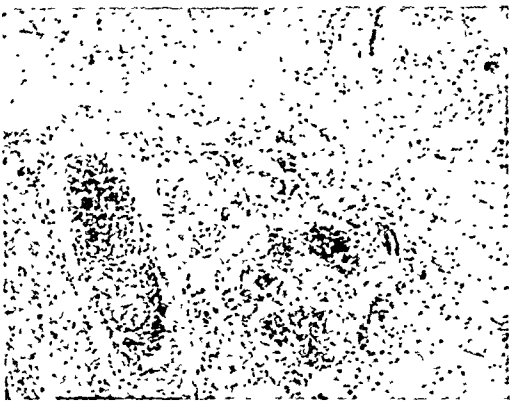

FIG. 4. W. B. Section showing thrombosis of a leptomeningeal arteriole, a branch of posterior cerebral artery, with acute cortical encephalomalacia.

the posterior portion of the adjacent fusiform gyrus. The area affected measures approximately 4 by 4.5 cm. at the surface. There was a similar change involving the right cuneus and posterior portion of the right lingual gyrus as well as adjacent portions of the posterior extremity of the right fusiform and inferior occipital gyri. The leptomeninges over this region showed irregular focal opacities. There was a small recent hemorrhage into the leptomeninges over the rostral portion of the ventral surface of the left side of the pons, measuring approximately 1.5 by 0.75 cm. The corresponding portion of the right side of the pons was deeply indented. The cerebellar tonsils were prominent and approximated toward the medulla. The arteries at the base of the brain showed a number of abnormal changes (Fig. 2). The left vertebral and the caudal portion of the basilar artery were slightly tortuous and showed marked thickening and irregularities of their walls owing to the presence of numerous confluent atheromatous plaques. The internal carotid arteries showed milder but similar changes. There was inequality in the two vertebral arteries, the right vertebral being of very small caliber for a distance of approximately 1.75 cm. before its junction with the left vertebral artery. The left vertebral artery was distended by a large mass of thrombotic material filling the lumen of the vessel. There was an ingrowth of fibroblasts from the intima.

Left occipital lobe: On section of the cerebrum, the swollen softened area described externally was found to involve the cortex and to extend into the subcortical white matter and to a slight extent into the subjacent centrum ovale (Fig. 3). The cortex in this region was discolored a greenish-yellow and was slightly swollen. The line of demarcation between gray and white matter was obscured.

The leptomeninges in the depth of a sulcus contained a large artery which was occluded and distended by thrombotic material. In the leptomeninges about the vessel there were considerable infiltration by lymphocytes, large mononuclear cells, and polymorphonuclears, most of which were intensely degenerated. The remainder of the leptomeninges up to and including the surface of the gyri was less intensely infiltrated and contained erythrocytes and lipoid-laden phagocytes. At the surface of the sulcus the exudate was again markedly degenerated. The underlying cortex showed acute diffuse necrosis with areas of somewhat more chronic malacia. The acute changes were marked by intense congestion, edema, hemorrhages, ischemic necrosis of ganglion cells, and varying degrees of infiltration, perivascular, focal, and diffuse (Fig. 4). A great many cortical capillaries contained hyaline thrombi. In many areas there was an intense necrosis of all neural, glial, and mesodermal elements, including the infiltrating cells. In the slightly older lesions there were lipoid-laden phagocytes and endothelial hyperplasia of the capillaries. The white matter was edematous and showed a lesser degree of diffuse degeneration.

Right occipital lobe: The lesions in the occipital region of this lobe extended to a similar depth in most of the areas involved. Posteriorly, it reached further into the centrum ovale.

A large leptomeningeal vessel was thrombosed, its wall undergoing necrosis. It contained a great deal of nuclear and cellular débris and some polymorphonuclear leukocytes. The leptomeninges were infiltrated by polymorphonuclear leukocytes, lymphocytes, and large mononuclear cells. Many of these showed intense degeneration. In the cortex there was acute necrosis of many of the nerve cells, the necrosis in many being of the ischemic type. There were intense degeneration of all of the glial elements and marked diffuse and some perivascular infiltration by cells similar to those seen in the leptomeninges. Many of the capillaries were thrombosed, the remainder being markedly hyperemic, and a great many recent pericapillary hemorrhages were present. There were similar hemorrhages into the subjacent white matter. The cortex of an adjacent gyrus showed a similar severe change. The nearby white matter, subcortical and central, contained a large area of older encephalomalacia. Here there

FIG. 2. W. B. Cross section of left vertebral artery showing arteriosclerosis and thrombosis.

X-rays: Antero-post., postero-ant., and left stereos of the skull showed the vault to be somewhat larger than usual, but it was not abnormal in thickness or shape. The sella turcica was normal in size and shape and was not atrophic. There was considerable calcification in the walls of the internal carotid arteries, particularly the left one. The pineal gland was not visible. The right mastoid was poorly developed and aerated; the left appeared to be normal. The sphenoid and petrous ridges were equal. Impression: moderate cerebral arteriosclerosis.

EEG: 16 lead eeg. with monopolar and bipolar recording. Disorganized EEG. Hyperventilation negative.

Course in hospital: During the period of hospitalization the patient had many transient attacks, often repeatedly in a single day, in which he became semiconscious and lethargic; he was confused and responded vaguely when questioned; his breathing was stertorous, and his eyes rolled from side to side, but no definitely convulsive manifestations developed. These attacks lasted about two minutes. Following these spells his vision became progressively diminished, and his memory disturbances became more marked. He complained quite consistently of severe headaches.

A re-examination on January 23, 1942, showed that he was almost completely blind with only variable appreciation between light and darkness. The retinal arteries showed some evidence of arteriosclerosis, and it was believed that spasm of the retinal arteries was responsible for the increase in his loss of vision. Vasodilators were used and for a time there seemed to be some response; the vision gradually improved, and he had a better appreciation of light and darkness. On one examination of the fields it was found that appreciation of light and dark was present at all points except in the inferior field in the left eye. It was then suspected that there might be some chiasmal lesion and an encephalogram was made on January 26, 1942, the results of which were as follows: Encephalogram after the withdrawal of 90 cc. of fluid and the injection of 85 cc. of oxygen showed the lateral and third ventricles to be normal in size, shape, and position. The aqueduct, fourth ventricle, and cerebral sulci appeared normal. The cisterna chiasmatis was obliterated, and there was a concave filling defect in the rostral portion of the cisterna interpeduncularis. The sulcal markings were well visualized over the right hemisphere, but only a few were noted on the left side. Impression: suprasellar tumor, probably a meningioma, possibly a pituitary adenoma, and, last, an aneurysm of the circle of Willis.

The x-ray of the skull showed that the patient had a moderate cerebral arteriosclerosis, but the interpretation of the encephalogram strongly suggested that there was some lesion in the vicinity of the optic chiasm, either vascular or adhesive in character, which had resulted in the obliteration of the cisterna chiasmatis and the production of the concave filling defect in the rostral portion of the cisterna interpeduncularis.

In the belief that there might be present a removable expanding lesion or possibly the presence of adhesions involving the optic chiasm, which could be separated, an operation for the exposure of the region of the chiasm was carried out on January 29, 1942, by Dr. Byron Stookey.

Following operation the patient showed considerable shock. He was in a stupor but would respond to pinprick. His temperature rose rapidly, his condition became worse, breathing became irregular and stertorous, there was evidence of circulatory failure, and in spite of supportive treatment the patient died on the evening following the day of his operation, the terminal temperature being 109 F.

Necropsy: Dr. Abner Wolf, the neuropathologist of the Neurological Institute, kindly supplied the following report of the postmortem examination. A complete necropsy was performed two hours postmortem on January 30, 1942. The results of the postmortem examination showed: sclerosis of the coronary arteries; cerebral arteriosclerosis; a congenital smallness of the right vertebral artery; thrombosis of the posterior cerebral and left vertebral arteries; encephalomalacia of both occipital lobes, old and recent; and recent softenings in the pons and thalamus; a fatty liver; bilateral lobular pneumonia; acute diverticulitis; nephrolithiasis; fibrous peritoneal adhesions; acute ulcerative proctitis; and acute splenic tumor.

Postmortem examination of the brain showed the following: weight 1,560 Gm. The cerebral hemispheres were asymmetric because of the flattening of the convex surface of the right frontal lobe. This had resulted from a considerable extradural operative hemorrhage in that region. The gyri in this zone were depressed and the sulci narrowed. Small recent hemorrhages on the surface of the right superior parietal lobule, the posterior portion of the left fusiform gyrus, and the inferior aspect of the right frontal pole medially were present. The more ventral of the inferior left occipital gyri was swollen, slightly protuberant, somewhat pallid, and quite soft to palpation. There was a similar change in

arterial disease was seen in the retinal arteries. There was a slight left central facial weakness.

Laboratory studies: Blood count: hemoglobin 14.8 Gm. (102 per cent); red blood cells, 4,540,000; smear, moderate macrocythemia; white blood cells 8,200; polymorphonuclears, 52 per cent; lymphocytes, 39 per cent; mononuclears, 4 per cent; eosinophils, 4 per cent; basophils, 1 per cent. Urinalysis: specific gravity, 1.004; reaction acid; albumin reaction, positive; no glucose or acetone; occasional red blood cell; rare white blood cell; occasional hyaline cast. Ventricular fluid: Total white blood cell, 3; red blood cell, 276; total protein, 16 mg. per cent.

X-ray of skull: Antero-post., postero-ant., and left lateral stereograms of the skull showed the vault to be of average thickness and not unusual in size or shape. There was advanced calcification in the walls of the internal carotid arteries. There was no evidence of increased intercranial pressure and the vascular channels, sella turcica, sphenoid, and petrous ridges appeared to be normal. The pineal gland was in the midline and by measurements was in its normal position. Impression: advanced cerebral arteriosclerosis.

A ventriculogram was performed under the impression that the patient was suffering from a right temporal infiltrating neoplasm. The ventriculogram showed the following: The lateral and third ventricles were somewhat enlarged, but they were in their normal position. The aqueduct and fourth ventricle were normal in size, shape, and position. The cerebral sulci appeared to be rather coarse. There was no evidence of a tumor. Impression: moderate, diffuse, bilateral cerebral atrophy, probably due to the arteriosclerosis. The negative ventriculogram and the evident arterial disease led then to the diagnosis of cerebral arteriosclerosis.

Course in hospital: the patient became somewhat drowsy and vision became obviously poorer. Fundus examination showed an advancing arteriolar disease with venous congestion, but no hemorrhages or patches of exudate. The patient continued to fail after ventriculography. The blood pressure on admission was 184/130 and presented rather wide fluctuations, reaching as low a level as 130/90 after the ventriculogram, and increasing to 208/148 as death approached.

Necropsy: Dr. Abner Wolf, the neuropathologist of the Neurological Institute, kindly supplied the following report of the postmortem examination. A complete necropsy was performed one and three-quarter hours postmortem on February 21, 1941. The results of the postmortem examination of the body showed the presence of generalized arteriosclerosis; thrombosis of both posterior cerebral arteries; encephalomalacia of both occipital lobes, the pons, and cerebellum; acute glomerulonephritis; advanced sclerosis of the coronary arteries; healed infarct of the left ventricular wall; cardiac hypertrophy and dilatation, calcification of the aorta; atrophy of the liver; cholelithiasis; fibrous pleural and peritoneal adhesions.

Postmortem examination of the brain showed the following: weight 1,420 Gm. The cerebral

FIG. 5. C. S. Cross section showing bilateral encephalomalacia of the calcarine and adjacent areas.

hemispheres were approximately symmetric. The gyri were well rounded and the sulci of normal width. The lingual gyri and adjacent ventral occipital gyri were soft to palpation but were not discolored (Fig. 5). The lateral extremity of the left cerebellar hemisphere showed an area of depression approximately 1.5 by 1 cm. in extent and 0.5 cm. deep. The folia were soft to palpation in this area and presented a grayish-yellow discoloration. A triangular zone anterior to this depressed lesion and measuring 2 by 1.5 cm. was soft but not sunken or discolored. The brain stem showed no external abnormalities. The arteries at the base of the brain were tortuous and showed focal dilatation and marked atheromatous changes in their walls. The most severe changes were those in the basilar and right vertebral arteries. The left vertebral artery was rudimentary, and the right vertebral artery was equal in caliber to the basilar artery. Atheromatous changes were also found in the smaller branches of the anterior, middle, and posterior cerebral arteries, but these were much less marked than those in the large basal vessels.

On section of the brain the areas of softening described externally in the occipital lobes were found to involve the lingual gyri and adjacent posterior extremity of the ventral occipital gyri. The cunei did not appear to be involved. The cortex of the affected gyri was swollen, yellowish-green, and friable.

The depressed lesion in the left cerebellar hemisphere showed chiefly atrophy and yellowish discoloration of the bordering folia. It appeared to be an older softening. A branch of the right posterior cerebral artery supplying the anterior portion of the softened area was filled with opaque, yellowish-white material. A small branch of the left posterior cerebral artery showed a reduction of its lumen to a narrow slit by dense, cream-colored material. The lateral and third ventricles were moderately dilated but showed no abnormalities of their walls.

Right posterior cerebral artery: The intima was markedly thickened, reducing the lumen of the vessel to a narrow space.

Left posterior cerebral artery: This vessel showed

was complete loss of neural and neuroglial elements with formation of irregular cysts in which numerous lipoid-laden phagocytes were present. There was, in addition, occasional perivascular infiltration by lymphocytes, large mononuclear cells, and eosinophils.

Section of the brain stem revealed a large, poorly outlined, irregular area of slight discoloration, edema, and softening in the basilar portion of the rostral extremity of the pons, chiefly to the right of the midline, but also extending somewhat toward the left. This type of change also extended into the midline of the tegmentum, reaching a point midway between its ventral and dorsal extremities. The architectural markings of the ventral portion of the middle of the tegmentum and of the left side of the reticular area were somewhat reduced. The parenchyma was essentially intact, however, in this zone. Examination of the optic nerve showed no evidence of demyelinization. The rest of the brain stem showed no gross abnormalities.

Comment: A review of this situation disclosed the fact that insufficient attention was paid to the transient obscurations of vision which took place, and to the irregular rolling movements of the eyes which accompanied what the patient described as "blackouts." The general description of these attacks resembled *petit mal* seizures, but the accompaniment of the seizures by the visual and oculomotor disorders should have indicated the fact that these were not typical *petit mal* seizures but were seizures of a similar nature originating from circulatory disturbances in the occipital lobes. Postmortem investigation demonstrated the fact that the arteriosclerosis, both general and cerebral, was far out of proportion to the clinical evidences found on physical and neurologic examination. The clinical picture was further obscured by the misleading results obtained by pneumencephalography, which seemed to indicate the presence of a remediable lesion in the vicinity of the optic chiasm. The pathologic findings in connection with the two vertebral arteries, the basilar, and both posterior cerebral arteries, afforded a complete explanation for the episodic attacks of visual obscuration and the eventual almost total blindness which the patient presented after his admission to the Neurological Institute. His transient attacks preceding the establishment of the final blindness substantiated the supposition that the attacks were due to temporary obstruction of the blood supply of the occipital lobe which finally, owing to the advance of the process, resulted in complete destruction and softening of both visual areas. The necropsy findings indicated repeated interferences with the circulation of the occipital lobes, the older ones coinciding quite accurately with the time of onset of the final picture.

Case 5.—Summary: A 62-year-old man developed symptoms of cerebral involvement over a period of three months. Physical examination disclosed arteriosclerosis, left pyramidal tract signs, and increasing blindness.

History: C. P. S. (633593), aged 62, was admitted to the Neurological Institute on February 10, 1941, and died on February 21, 1941. The record of this patient was made available to us through the courtesy of Dr. Byron Stookey.

The chief complaints were: (1) ringing in the ears; (2) dizzy spells; (3) numbness and weakness of the left arm and leg for three months, and (4) blurring of vision for three months. The ringing in the ears had been present as a constant noise, noticed only when the patient was in quiet surroundings, for several years before admission to the hospital. There had been no material impairment in hearing, and no hallucinatory experiences had occurred.

In the early part of 1940 the patient began to suffer from attacks of dizziness, usually brought on by leaning forward. The room seemed to him to revolve, usually from left to right. These attacks increased progressively in frequency and severity. The dizziness affected his gait, causing it to be unsteady, and he required support. He was very unsteady in walking at night.

Since November, 1940, he had been conscious of numbness and tingling in his left lower extremity. This occurred at intervals and later spread to involve the left hand and forearm. Recently it had affected the right leg and foot also. During these spells of numbness and tingling there had been some weakness in the extremity, but not in the intervals between attacks.

Diminution in vision had been noticed also since November, 1940, and although glasses were prescribed, they afforded no relief. The difficulty first involved near vision, but later distant objects also were obscured. There had been no material headache.

There was no history of cardiovascular disease in the family.

The patient's past history was unimportant. He had two children, living and well.

Examination: The general physical examination showed some vascular pigmented nevi. There was slight edema of the ankles. The heart was enlarged to the left, the apex impulse being 14 cm. to the left of the midsternal line. An apical systolic murmur was present. The palpable blood vessels were thickened and tortuous. The liver was palpable 3 cm. below the costal margin and a large, right, reducible inguinal hernia was present.

Neurologic examination: The patient was right-handed. There was a fine tremor of the hands which was made worse on intentional movements. There was a generalized hypotonicity. There was some slowness in performing succession movements in the right upper extremity. The reflexes were underactive, but equal. Abnormal reflexes were obtained from both plantar surfaces, and definite Babinski and confirmatory signs were elicited from the left foot. Examination of the visual fields showed a marked concentric reduction in the visual fields, with particular involvement of the upper left homonymous field. Another examination of the visual function showed a visual acuity of 10/200; the only retained field consisted of a narrow, concentric zone in the right lower homonymous fields. Examination showed that the disks were hyperemic and swollen, each measuring one diopter. Evidence of advanced

arterial disease was seen in the retinal arteries. There was a slight left central facial weakness.

Laboratory studies: Blood count: hemoglobin 14.8 Gm. (102 per cent); red blood cells, 4,540,000; smear, moderate macrocythemia; white blood cells 8,200; polymorphonuclears, 52 per cent; lymphocytes, 39 per cent; mononuclears, 4 per cent; eosinophils, 4 per cent; basophils, 1 per cent. Urinalysis: specific gravity, 1.004; reaction acid; albumin reaction, positive; no glucose or acetone; occasional red blood cell; rare white blood cell; occasional hyaline cast. Ventricular fluid: Total white blood cell, 3; red blood cell, 276; total protein, 16 mg. per cent.

X-ray of skull: Antero-post., postero-ant., and left lateral stereograms of the skull showed the vault to be of average thickness and not unusual in size or shape. There was advanced calcification in the walls of the internal carotid arteries. There was no evidence of increased intercranial pressure and the vascular channels, sella turcica, sphenoid, and petrous ridges appeared to be normal. The pineal gland was in the midline and by measurements was in its normal position. Impression: advanced cerebral arteriosclerosis.

A ventriculogram was performed under the impression that the patient was suffering from a right temporal infiltrating neoplasm. The ventriculogram showed the following: The lateral and third ventricles were somewhat enlarged, but they were in their normal position. The aqueduct and fourth ventricle were normal in size, shape, and position. The cerebral sulci appeared to be rather coarse. There was no evidence of a tumor. Impression: moderate, diffuse, bilateral cerebral atrophy, probably due to the arteriosclerosis. The negative ventriculogram and the evident arterial disease led then to the diagnosis of cerebral arteriosclerosis.

Course in hospital: the patient became somewhat drowsy and vision became obviously poorer. Fundus examination showed an advancing arteriolar disease with venous congestion, but no hemorrhages or patches of exudate. The patient continued to fail after ventriculography. The blood pressure on admission was 184/130 and presented rather wide fluctuations, reaching as low a level as 130/90 after the ventriculogram, and increasing to 208/148 as death approached.

Necropsy: Dr. Abner Wolf, the neuropathologist of the Neurological Institute, kindly supplied the following report of the postmortem examination. A complete necropsy was performed one and three-quarter hours postmortem on February 21, 1941. The results of the postmortem examination of the body showed the presence of generalized arteriosclerosis; thrombosis of both posterior cerebral arteries; encephalomalacia of both occipital lobes, the pons, and cerebellum; acute glomerulonephritis; advanced sclerosis of the coronary arteries; healed infarct of the left ventricular wall; cardiac hypertrophy and dilatation, calcification of the aorta; atrophy of the liver; cholelithiasis; fibrous pleural and peritoneal adhesions.

Postmortem examination of the brain showed the following: weight 1,420 Gm. The cerebral

FIG. 5. C. S. Cross section showing bilateral encephalomalacia of the calcarine and adjacent areas.

hemispheres were approximately symmetric. The gyri were well rounded and the sulci of normal width. The lingual gyri and adjacent ventral occipital gyri were soft to palpation but were not discolored (Fig. 5). The lateral extremity of the left cerebellar hemisphere showed an area of depression approximately 1.5 by 1 cm. in extent and 0.5 cm. deep. The folia were soft to palpation in this area and presented a grayish-yellow discoloration. A triangular zone anterior to this depressed lesion and measuring 2 by 1.5 cm. was soft but not sunken or discolored. The brain stem showed no external abnormalities. The arteries at the base of the brain were tortuous and showed focal dilatation and marked atheromatous changes in their walls. The most severe changes were those in the basilar and right vertebral arteries. The left vertebral artery was rudimentary, and the right vertebral artery was equal in caliber to the basilar artery. Atheromatous changes were also found in the smaller branches of the anterior, middle, and posterior cerebral arteries, but these were much less marked than those in the large basal vessels.

On section of the brain the areas of softening described externally in the occipital lobes were found to involve the lingual gyri and adjacent posterior extremity of the ventral occipital gyri. The cunei did not appear to be involved. The cortex of the affected gyri was swollen, yellowish-green, and friable.

The depressed lesion in the left cerebellar hemisphere showed chiefly atrophy and yellowish discoloration of the bordering folia. It appeared to be an older softening. A branch of the right posterior cerebral artery supplying the anterior portion of the softened area was filled with opaque, yellowish-white material. A small branch of the left posterior cerebral artery showed a reduction of its lumen to a narrow slit by dense, cream-colored material. The lateral and third ventricles were moderately dilated but showed no abnormalities of their walls.

Right posterior cerebral artery: The intima was markedly thickened, reducing the lumen of the vessel to a narrow space.

Left posterior cerebral artery: This vessel showed

a less marked, but considerable, thickening of its intima, which resulted in a definite reduction in the lumen of the vessel.

Right occipital lobe: The leptomeninges were edematous, congested, and showed considerable hyperplasia of the leptomeningeal elements. Some of the smaller arteries contained amorphous pink material which partially filled their lumina. One of these showed a partial occlusion of the lumen by this material. A number of the medium-sized arteries showed thickening of their intima. One small artery showed almost complete occlusion of its lumen by thrombotic material with a beginning ingrowth of fibroblasts. The cortex in this entire region showed marked softening which varied in age in different areas. For the most part, it was quite acute. The nerve cells had undergone ischemic necrosis, and many of them had disappeared. There was also widespread degeneration of the neuroglial elements in these areas without any mobilization of microglia or any endothelial hyperplasia of the blood vessels.

Some of the cortical vessels in these zones were filled by masses of pink amorphous material. In one such area small masses of hematoidin were found scattered near the margin of the zone, where it abutted upon a more chronic softening. Here the cortical architecture had disappeared, the nerve cells and most of the neuroglial cells having been destroyed. The tissue was cribriform and contained many lipoid-laden phagocytes. In a nearby sulcus, an arteriole showed almost complete occlusion of its lumen because of extreme thickening of its intima. There were some areas of more chronic softening in the subcortical white matter as well. The best preserved cortex was in the calcarine area. Phosphotungstic acid stain: There was mild to moderate astrocytosis at the margins of the older areas of softening.

Left occipital lobe: A medium-sized artery in the calcarine fissure was distended by a thrombotic mass, which almost completely filled it. The cortex of the gyri on either side of the fissure showed intense degeneration, as did part of the underlying white matter. Here again the degeneration was both acute and chonic, the major portion of it being acute. In the areas of more recent necrosis, the nerve cells showed ischemic degeneration and there was degeneration of the neuroglial and microglial cells. The blood vessels showed degeneration of their walls, and there were scattered small hemorrhages. Some of the smaller leptomeningeal and many of the cortical vessels were filled with amorphous pink material. The more chronic softenings showed the same appearances as those described in the right occipital lobe, with endothelial hyperplasia of the walls of the capillaries, in addition. The softening of the white matter was milder, and was both acute and chronic. Phosphotungstic acid stain: The findings were similar to those described in the right occipital lobe.

Comment: This patient presented the picture of cerebral arteriosclerosis with some evidence of focal involvement of the right hemisphere, followed by a similar situation in the left hemisphere. A gradual encroachment upon vision took place with eventual almost complete blindness due to symmetric vascular involvement of both occipital lobes.

Case 6.—Summary: A 38-year-old woman gradually became aware of a loss of vision in the right eye. Ventriculography disclosed a neoplasm of the occipital region which was removed at operation.

The following case history is introduced into this discussion not because of the presence of a total blindness but because of the presence of a right homonymous hemianopsia with an invasion of the left homonymous field of vision. It was believed that if the condition had been allowed to progress, a continuing and advancing involvement of the right calcarine area would have produced a complete blindness because of bilateral destruction of the calcarine areas.

History: M. S. (661823) aged 38, a housewife, was admitted to the Neurological Institute December 1, 1941, and discharged December 8, 1941. The record of this patient was made available to us through the courtesy of Dr. Cornelius G. Dyke.

She complained of difficulty in seeing objects to the right for the past ten days. Her visual difficulty was attracted to her attention by the fact that during the past ten days she found she did not see the last two words of each printed line as she read. On reconsideration, she believed that for the past four or five months she had been less aware of cars approaching her from the right, and in October she had scraped the right running board of her car against the side of a bridge. She later noticed that she bumped into people who approached her from the right. Her actual visual acuity was not changed, and she had no difficulty in threading a needle.

During the past several months she had had some headache in the early morning, which was generalized, and improved after she had been moving about for a time. There was no exacerbation of the headache with coughing or changes in position. Once shortly before examination, during defecation, she experienced a sharp, knife-like pain across the back of the neck.

The past history was uneventful except that in March, 1940, she contracted an otitis media in the left ear, which ruptured and drained. X-ray of the mastoid showed a simple mastoiditis, which was operated upon and healed after about five weeks of drainage. The infecting agent was understood to be a type III Pneumococcus. Audiometric examination made later showed some impairment in the hearing of the left ear. She had not suffered from any vertigo, dizziness, or tinnitus. In September, 1941, she struck her head quite severely against a low ceiling but was not dazed or incapacitated.

Examination: There was no general systemic abnormality. She was left-handed. There was some reduction in the automatic movements of the right arm in walking. There was no inequality in the reflex responses. The abdominal reactions were questionable, and moderate bilateral plantar flexion was present. There was no change in the superficial, deep, or cortical types of sensibility. No agnosias were present. On gross testing she was found to have a right homonymous hemianopsia with an homonymous invasion of the left fields of vision

(Fig. 6). The pupils measured 3 mm. in diameter and reacted normally. There was no limitation of ocular movements. Hearing in the left ear was somewhat impaired, and the bone-air conduction formula was reversed: hearing was lateralized to the left. Audiograms showed a slight reduction in hearing in the left ear for low tones.

Laboratory studies: Blood count—hemoglobin, 10.5 Gm. (72 per cent); red blood cells, 3,820,000; smear, slight anisocytosis; white blood cells, 10,600; polymorphonuclears, 69 per cent; lymphocytes, 26 per cent; mononuclears, 3 per cent; eosinophils, 2 per cent. Blood chemistry—nonprotein nitrogen, 30 mg. per cent; sugar, 105 mg. per cent. Blood Kline test—negative. Sugar tolerance test—fasting, 105 mg. per cent; one-half hour, 136 mg. per cent; one hour, 103 mg. per cent; two hours, 88 mg. per cent; three hours, 84 mg. per cent; four hours, 130 mg. per cent. Urinalysis—specific gravity, 1.006; reaction, alkaline; no albumin, glucose, or acetone; no red blood cells; occasional white blood cells; no casts. Spinal fluid—total protein, 62 mg. per cent; total white blood cells, 2; Colloidal gold—1,100,000,000. Wassermann reaction was negative. Basal metabolism was −20 per cent; test satisfactory.

X-rays, antero-post., and postero-ant., basal, cerebellar and left lateral stereograms of the skull, and a film of the optic foramina showed the vault to be of average thickness and not unusual in size or shape. The posterior clinoid processes and the dorsum sellae appeared unusually thin and delicate, without direct evidence of atrophy. The sella turcica was not unusual in size or shape. The vascular channels and sutures did not appear unusual. The superior ridge of the left petrous pyramid from the arcuate eminence medially was less dense than the right. A bony defect was present in the left mastoid. The pineal gland was displaced 4.5 cm. to the right of the midline, and by measurements it was at the posterior limits of the normal zone in the antero-post. plane, but was well within the normal zone in the vertical plane. Impression: left cerebral tumor; the decalcification of the medial half of the superior margin of the left petrous pyramid suggested that the lesion was located here. An epidermoid, either extra- or intradural was believed to be the type most likely capable of producing the changes that have been described.

However, in view of the mastoidectomy, it was considered possible that the condition was an extradural abscess.

Encephalograms taken after the withdrawal of 75 cc. of fluid and the injection of 70 cc. of oxygen failed to show any gas in the ventricular system. There was considerable gas in the subdural, subtentorial space, and on the left side the gas shadow was somewhat irregular and formed an abnormal curve.

There was also some gas in the subdural space over the right cerebral hemisphere. This did not appear unusual in the antero-post. or postero-ant. views. There was some gas around the splenium of the corpus callosum, seen in the left upright lateral stereograms, and it had a more angular appearance

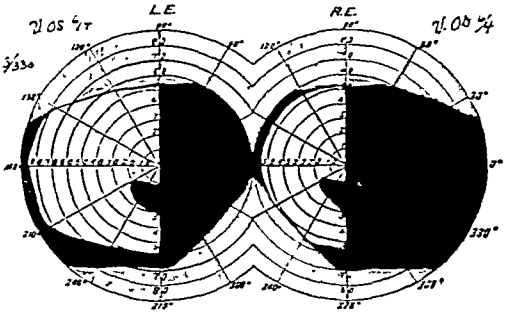

FIG. 6. (M.S.) Visual fields showing complete right homonymous hemianopsia and beginning encroachment upon the left homonymous fields, produced by a meningioma arising from the falx, destroying the left visual area, with extension through the falx and involvement of the right calcarine area.

than usual. The gas in the central portion of the cisterna ambiens was displaced to the right. There was some gas in the cisternae pontis and interpeduncularis, and this did not appear unusual. In the right horizontal lateral stereograms there was a rather unusual shadow in the occipital area to the right of the midline which was interpreted as normal brain outlined by subdural gas on the medial aspect of the right occipital lobe. It was believed that this peculiar shadow was due to pressure from the left occipital lobe against the falx in contact with the medial surface of the right occipital lobe. There was gas in the left sylvian fissure, and these gas shadows appeared to be cut off and somewhat deformed. A few sulcal markings were seen on the right side.

There was some gas in the subarachnoid space and over the vermis of the cerebellum. Impression: The evidence indicated a left cerebral mass located just above the left petrous pyramid, and it was believed that the lesion was an epidermoid, probably subdural.

Following the encephalogram there was some slight increase in reflex activity consistently found in the left extremities. There was slight swelling of the upper pole of each optic disk, seen best with a plus 2 lens. The nasal margins appeared to be slightly hazy.

The examination of the patient and a study of the visual fields indicated the presence of a neoplasm.

Since the gas introduced at the time of the encephalogram had failed to enter the ventricular cavity and the clinical indications as to the localization of the neoplasm were not clear, it was believed that ventriculography was indicated. Since emergency operation is sometimes necessary after the performance of ventriculography and since it was desired to have any operative procedures carried out at the Mayo Clinic, it was decided to postpone further studies and have the final steps carried out there. Consequently the patient was transferred to the Clinic, where she

was studied by the neurosurgical staff. We are indebted to Dr. W. McK. Craig for information as to the further investigation of the patient.

A complete revaluation of the clinical situation was carried out and the principal features previously disclosed were corroborated. On account of obvious discrepancies in the symptoms and physical signs and the peculiar shadow discovered by the x-ray examination made at the Neurological Institute, further x-ray studies were made. Because of the shift of the pineal gland disclosed in previous x-rays of the skull, it was suspected that the lesion was farther back than the temporal lobe and the optic chiasm. For that reason, ventriculograms were made which revealed a large space-occupying lesion in the left occipital lobe. At operation this proved to be a meningioma which extended from the surface of the cortex to the falx, to which it was attached. The tumor had invaded the falx, and there was a small portion of the tumor on the right side of the falx. The tumor proved to be a cellular meningioma which had replaced practically the entire occipital lobe and it was removed by resection of the left occipital lobe and the involved portion of the falx.

The patient successfully passed through the operation and convalesced satisfactorily. A slight aphasia developed immediately after the operation, but it completely cleared up.

Comment: This patient presented a meningioma which had destroyed the left calcarine area and was in the process of encroaching upon the corresponding cortical area of the right occipital lobe. If this process had been carried to its logical conclusion, she would have been completely blind from the bilateral effect of a neoplasm arising from the occipital portion of the falx.

Summary and Conclusions

The visual pathways from the corneas to the occipital poles are reviewed from a clinico-anatomic standpoint with special reference to bilateral blindness. Bilateral blindness due to lesions in both occipital lobes may be caused by subcortical degenerative processes, trauma, tumors, toxic encephalopathy, and vascular lesions.

Vascular lesions produce bilateral blindness through occlusion of both posterior cerebral arteries, or complete occlusion of the basilar artery. In these cases some central (macular) vision may be retained if the occipital poles have an additional blood supply from the branches of the middle or anterior cerebral arteries. In some cases the visual area is affected primarily by changes in the small terminal vessels, as in Case 3.

Of the 6 reported cases, 4 were caused by vascular lesions and were verified by autopsy. One case was due to metastatic carcinoma of the stomach and another was due to a meningioma.

Bilateral blindness, when not due to discernible changes in the media, choroid, retina, optic nerve, or, in early stages, to chiasmal field changes, must be considered as being due to bilateral lesions in the geniculo-calcarine pathways especially the occipital lobes, or to psychi causes. The insidious onset of the blindnes and the masking by the associated symptom make an early diagnosis difficult.

Discussion

Dr. W. B. Hamby, *Buffalo*—This topic is of great importance to the neurologist and his colleagues, and since the number of reported cases is small, I should like to record another case of blindness due to occipital polar abscesses.

Case Report

A 24-year-old white railroad maintenance worker was examined by the Draft Board on August 30, 1941, and his vision measured 20/20. His status was not settled but he was considered deferable because of a left lung abscess diagnosed five years before and considered clinically cured.

On September 18, 1941, while at work, he developed a sudden severe frontal headache and went home. The pain was relieved by medication, and he returned to work the next day. Three days later he suddenly noticed dazzling light before him, and he became blind. On September 24 he vomited and had headache, emesis continuing for two days.

On September 26 the patient was brought to my office. He was a powerfully built young man and was guided in by his father and brother, who were holding his arms. In spite of this, he encountered obstacles. When put before a chair and told to sit, he did not grope for it, as the blind do, but launched himself at it so as to sit half on the seat and half on the arm. Since he proclaimed his blindness loudly, he was told to walk through a cleared path in the room. Apparently he would go out of his way to walk into furniture. Careful neurologic examination revealed no abnormalities except the subjective blindness.

I was inclined to consider this a case of hysterical blindness precipitated by worry over military possibilities, but his physician insisted that he had no reason to fear being drafted. The patient was admitted to the Buffalo General Hospital on September 29.

On examination in the hospital, the patient apparently was in discomfort and kept his eyes closed most of the time. The skull was normal to clinical and roentgenographic examination. The ocular movements were full and free, with a few nystagmoid motions on lateral gaze. The pupils were round, equal, and regular, and they reacted to light. The patient would not accommodate to his own finger. The retinas and optic disks appeared normal. Vision was difficult to evaluate; the patient would be

FIG. 7. Left—View of lower half of brain showing abscess in both occipital poles and edema of white matter particularly on left side. Right—Upper half of hemispheres, same case.

completely blind in all fields to an object or a light shortly after saying he could see the examiner. The neurologic examination otherwise was normal.

The heart was normal to examination, his blood pressure was 130/85, and his pulse was 70. The chest examination gave evidence of old fibrosis in the left lower lung.

Blood counts on two occasions showed no gross abnormality. A lumbar puncture revealed increased pressure. The fluid contained 186 white blood cells, with 95 per cent lymphocytes and 130 mg. of total proteins.

On October 1, 1941, an encephalogram was attempted, but no air entered the cranium. Trephines then were made 6 cm. above and 3 cm. to each side of the inion for ventriculography. When the dura was incised, brain substance protruded. A cannula was introduced in search of the left lateral ventricle and about 3 cm. from the surface, encountered an abscess without a definitely palpable capsule. Fifteen cubic centimeters of thick, creamy yellow, foul-smelling pus was aspirated. A second cannula was introduced on the right side and another abscess was encountered, 2 cm. from the surface. Fifteen cubic centimeters of similar pus was aspirated. While the trephine openings were being enlarged, the patient had a fit of coughing and expectorated a large quantity of pus very similar to that found in the brain. Rubber tissue drains were introduced into each abscess, and the wounds were dressed. No organisms grew on aerobic or anaerobic cultures of the pus and cerebrospinal fluid.

The patient did well for several days. He never again expectorated pus or complained of pulmonary symptoms. About a week later, however, he began to have peculiar emotional changes, with alternating periodic rages and depressions. The abscesses drained well and the spinal fluid pressure was elevated to around 300 mm. of water. After an early improvement, vision again failed. With the great emotional changes, another frontal lobe abscess was suspected. The patient died suddenly on the eleventh postoperative day.

Postmortem examination revealed an abscess filling out the entire left occipital pole and extending laterally and upward into the parieto-occipital region. It measured 4 by 5.5 cm. This abscess showed a somewhat irregular recess-like extension upward and medial, forming an almost separate abscess about 3 cm. in diameter. Both were filled with a decidedly fetid, rather tenacious, greyish-yellow, purulent exudate. The surrounding tissue showed unusually marked collateral edema with almost actual colliquation and considerable edema of the entire white matter, with marked swelling of the cortex. This was present throughout the left hemisphere, especially marked at the convexity. The abscess closely approached the posterior horn, which appeared considerably compressed but not invaded.

In the right occipital pole there was an abscess, measuring about 2 cm. in sagittal and 1.5 cm. in frontal diameters. All the abscesses were surrounded by a well-formed pyogenic membrane. The surrounding tissue also showed distinct colliquation necrosis and considerable edema throughout the white matter, with somewhat less marked swelling of the right hemisphere. Especially the left occipital area showed extreme bulging in all directions, obviously pressing upon the tentorium. Both lateral

ventricles contained a fair amount of clear spinal fluid.

The fourth ventricle, however, appeared almost entirely compressed, with only a few drops of spinal fluid. There was no spinal fluid in the basal cisternae, all of which appeared compressed by the decidedly swollen brain stem.

Smears taken from each abscess showed a considerable number of very thin, gram-negative, fusiform bacilli, some of which had a fairly typical whip shape, while others looked like almost entirely stretched spirochetes.

Examination of the lungs revealed chiefly purulent bronchiectasis, especially of the left lower lobe. Smears of pus from these areas revealed the same "whip-shaped" organisms.

STERILIZATION OF AIR IN CLOSED SPACES

The circumstances of modern warfare frequently necessitate the herding together of large numbers of people in air raid shelters. The control of air-borne infections in confined areas has therefore become a particularly urgent problem. A necessary preliminary to the scientific study of a problem of this nature is the establishment of experimental methods by which the various factors involved can be satisfactorily varied and controlled. For this purpose Edward, Elford, and the late Sir Patrick Laidlaw have described a method for the experimental investigation of aerosol systems formed by the atomization of suspensions of viruses into the atmosphere. They have performed observations on the physical properties of such systems and found an experimental approach to certain practical problems connected with air-borne virus infections.

In additional work also from the National Institute for Medical Research in London, Edward, Lush, and Bourdillon describe quantitative studies carried out early in 1940 on the killing effect of ultraviolet radiation on aerosols of three different viruses: influenza A, vaccinia, and herpes simplex.

Using the experimental methods now established as reliable for observations of this kind, these workers showed that rapid and effective sterilization of atmospheres containing atomized particles of influenza and vaccinia viruses, and probably also of herpes simplex virus, can be obtained by ultraviolet radiation of wavelength 2,537 angstroms.

An additional recent contribution to the subject by Challinor, of the University of Edinburgh, is concerned solely with the action of hypochlorite on the total bacterial content of the air of an occupied closed room under fixed conditions of ventilation. He obtained a substantial reduction in the bacterial content of the air of an empty room infected with Bacillus prodigiosus (or with Staphylococcus albus or a diphtheroid bacillus) by means of hypochlorites introduced into the air by atomization or by spraying from a flit gun. The relative humidity of the air has been previously shown to be a factor of great importance in the effectiveness of air disinfection. In Challinor's experiments likewise effective air-disinfection was not obtained at low relative humidities at temperatures ranging from 54 to 74 F. More accurate determination of the critical lower limit of relative humidity is desirable. Ultraviolet irradiation, propylene glycol vapor, as reported by Robertson and his colleagues, and now hypochlorite solution all appear to exert bactericidal and bacteriostatic effects on the atmosphere of closed air spaces. The experimental methods for controlling the factors involved are now available so that it remains only to choose what method or combination of methods can be most effectively employed in actual practice.—*J.A.M.A.*

OPPORTUNITY TO STUDY ARMY AND NAVY TREATMENT OF CASUALTIES

An opportunity to study Army and Navy treatment of casualties at two of the nation's leading military hospitals will be afforded physicians attending the annual convention of the Association of Military Surgeons of the United States in Philadelphia on October 21–23, inclusive.

Visits to the U.S. Naval Hospital, Philadelphia, and the U.S. Army Hospital at Valley Forge, where patients from war zones are under treatment, may be arranged for members of the Association during the three-day convention at the Bellevue-Stratford if they so wish.

The Army Hospital is near the site of George Washington's winter headquarters in the bitter season of 1777–1778. Its location accentuates the fact that the 1943 convention will be held in a city rich in both military and medical history.

Philadelphia rightly claims the distinction of being the birthplace of the nation and of American medicine. Here the Declaration of Independence was signed. Here also were founded the first medical school, the first hospital, and the first woman's medical college.

The College of Physicians was formed in Philadelphia during the same year that the Constitution of the United States was being written there. Two of the founders of the College of Physicians, Dr. Benjamin Rush, of Pennsylvania, and Dr. James McHenry, of Maryland, were among the signers of the Declaration of Independence.

The Navy's Bureau of Medicine and Surgery was established originally in Philadelphia.

Throughout the years Philadelphia has maintained its high place in medical circles and today boasts of six of the country's outstanding medical schools. They are: The University of Pennsylvania, Graduate School, Jefferson, Temple, Hahnemann, and the Woman's Medical College.

THE SIGNIFICANCE OF INCREASED MENSTRUAL BLEEDING IN WOMEN OVER FORTY

CLYDE L. RANDALL, M.D., Buffalo

IN 1926, the Council of the Medical Women's Federation (England)[1] appointed a committee to investigate the clinical aspects of the menopause. The conclusions of this group were based upon an analysis of the data collected from 1,200 questionnaires. The attention accorded this subject by others writing at the time is indicated by Fitzgibbon,[2] who, in 1932, was among the first to enumerate "suggested criteria of the normal menopause." However, neither the report of the Medical Women's Federation nor Fitzgibbon's study considered the significance of changes in the amount of the menstrual flow during the menopausal years.

Menorrhagia at the Menopause

The significance of increased menstrual bleeding at the time of the menopause has been discussed in a number of authoritative reviews of the subject. Keene,[3] Payne,[4] Norris,[5] Crossen and Crossen,[6] and Taylor and Millen[7] have all analyzed large series of cases and have presented valuable data concerning the cause of increased bleeding at the time of the menopause. In view of their studies the causes of menorrhagia among women in this age group will not be detailed in this report.

TABLE 1

TOTAL HISTORIES CONSIDERED

PATIENTS' AGE	GROUP	NO. of PATIENTS	
OVER 40	COMPLAINTS-OTHER THAN BLEEDING (Still having regular periods)	493	
OVER 40	COMPLAINT- MENSTRUAL EXCESS or IRREGULARITY	683	
TOTAL PATIENTS SEEN BEFORE MENOPAUSE			1176
OVER 40	MENOPAUSE after SURGERY or RADIATION	143	
OVER 40	AMENORRHEA of 6 to 12 MONTHS DURATION	23	
OVER 40	AMENORRHEA LONGER THAN 12 MONTHS	650	
TOTAL PATIENTS SEEN AFTER MENOPAUSE			816
Total number of histories of women over 40		1992	1992

The frequency of increased bleeding during the change of life is evident in the figures shown in Table 1. For this report the menstrual histories of 1,992 patients over 40 years of age have been analyzed, and of this number 1,176 were seen prior to cessation of their periods. Of the women seen before their menopause, 683, or 58 per cent, sought medical advice because of irregular or increased menstrual flow. Among the patients over 40, 816 were interviewed after their menopause and of this number 650 had noted no bleeding for longer than a year following spontaneous cessation of their periods.

TABLE 2

COMPLAINT: INCREASED MENSTRUAL BLEEDING
683 patients over 40: before the menopause

PROCEDURE ADVISED	NO. of PATIENTS	INCIDENCE
OFFICE MANAGEMENT	160	23.4 %
To HOSPITAL for SURGERY GROSSLY APPARENT PATHOLOGY	280	41 %
To HOSPITAL for DIAGNOSIS PATHOLOGY NOT GROSSLY APPARENT	243	35.6 %

Considering the 683 patients over 40 years of age who sought medical advice because of increased bleeding before the menopause (Table 2), it is apparent that only 160 patients, or 23.4 per cent, of the group were treated in the office. Among this group an easily removed cervical polyp or obviously functional menorrhagia were the most frequent causes for the increased bleeding. It will be noted that hospitalization was advised for 3 of every 4 patients among these 683 women. In 35.6 per cent there was apparently no gross pathology to account for the bleeding; therefore hospitalization and curettage were advised as a means of establishing a diagnosis.

TABLE 3

INCIDENCE of MALIGNANCY as the CAUSE of INCREASED BLEEDING
523 women before the menopause: hospitalization advised

CAUSE of BLEEDING	INCIDENCE
FIBROMYOMAS of UTERUS COINCIDENTAL MALIGNANCY - 1 CASE	48.4 %
ENDOMETRIAL HYPERPLASIA NO APPRECIABLE FIBROID	17.6 %
POLYPS NO COINCIDENTAL MALIGNANCY	11.2 %
MISCELLANEOUS - NON-MALIGNANT	17.4 %
MALIGNANCY IN UTERI WITHOUT FIBROIDS — 10.3%	5.3 %

Table 3 illustrates the almost universal observation that fibroids of the uterus are found in fully one-half the women with menorrhagia during the menopausal years. The incidence of malignancy, 5.3 per cent, is certainly high enough to emphasize the necessity of employing measures adequate to eliminate the possibility of carcinoma in every woman whose flow increases after 40 years of age.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 4, 1943.

From the Department of Obstetrics and Gynecology of the Buffalo General Hospital and the University of Buffalo.

Malignancy at the Menopause

According to a recent statement of one of the largest life insurance companies,[8] 5 of every 200 women reaching the age of 40 now die of carcinoma of the uterus. However, a single figure may not satisfactorily express the incidence of malignancy as the cause of increased menstrual flowing in women over 40. In Table 3, it may be noted that when patients with grossly appreciable fibroids are excluded from consideration, malignancy of the uterus was found in 10.3 per cent of women complaining of increased bleeding before the menopause. Since this figure included cases in which the diagnosis of malignancy was evident grossly, it does not represent the incidence of suspected or unsuspected malignancy proved only on curettage. An effort was made to determine the incidence of early carcinoma of the fundus when women experiencing only increased bleeding are curetted at the time of the menopause. In Table 4, it will be noted that adenocarcinoma of the uterus was found in 9.1 per cent of 165 women with a grossly normal uterus curetted on account of menorrhagia at the menopause.

TABLE 4

INCIDENCE of MALIGNANCY
165 women: Complaint - increased bleeding before menopause
Apparently normal uterus - curetted for diagnosis

ADENOCARCINOMA	15 CASES
INCIDENCE	9.1 %

Irregular bleeding at the menopause is difficult to interpret because cessation of the periods usually involves some irregularity of the flow. During the past fifteen years Novak[9] has repeatedly clarified the symptomatology of the menopause, always with emphasis on the necessity of eliminating malignancy of the uterus whenever there is an increased menstrual flow during the menopausal years. King,[10] Pemberton,[11] Dougal,[12] and others have likewise stressed the importance of a diagnostic curettage whenever increased menstrual flowing occurs in women over 40 years of age. Obviously it is desirable to recognize criteria by which the changes in menstrual flow incidental to the menopause may be distinguished from abnormal bleeding that requires a careful search for early malignancy.

Criteria of Normal Bleeding at the Menopause

The literature includes many considerations of increased bleeding at the time of the menopause in which it is either stated or assumed that the normal change involves either a gradual or an abrupt cessation of the menstrual flow. Abnormal bleeding has been frequently discussed, but there has been scant reference to the reliability of the generally accepted norm. Moreover, the literature suggests no universal agreement as to when an increase in menstrual flow at the time of the menopause indicates a search for pathology. Fitzgibbon, for instance, speaks of the patient whose history he presents as exhibiting menorrhagia considered "as usual associated with the approach of the menopause." Frequently quoted is Drips'[13] employment of Zondek's classification of menopausal disturbances, in which so-called "Period 1" is designated as the months in which more frequent or excessive menstruation occurs. Many clinicians are prone to regard the statements of Novak, Whitehouse,[14] and others (referring to the fact that women with an increased flow at the menopause have less severe flushes and emotional instability) as an acceptance of an increased flow as a part of the normal menopause.

Several years ago a search of the literature failed to reveal a report in which statistics had been presented to illustrate the characteristics of menstruation during normal cessation of the flow. There seemed to be no data supporting the frequently expressed opinion that a majority of women experience no increased flow preceding final cessation of their periods. Since that time, in every suitable postmenopausal patient contacted in an office practice, a careful history has been taken with respect to the amount and regularity of the menstrual flow during the menopausal years. In this manner, data have been collected on the relative frequency of increased bleeding as compared with the occurrence of a gradual or abrupt cessation of the flow at the time of the menopause. To insure uniformity of interpretation, all the histories considered were taken by one individual.

TABLE 5

INCIDENCE of MENORRHAGIA at MENOPAUSE

GROUP	NO. of PATIENTS		INCIDENCE	
CESSATION after SURGERY or RADIUM	143			
CESSATION within 6 to 12 MONTHS	23			
INACCURATE DATA REGARDING MENORRHAGIA	106			
TOTAL HISTORIES DISCARDED		272		
CESSATION LONGER THAN ONE YEAR No menorrhagia prior to cessation	440		80.9%	
(Complaint postmenopausal bleeding)		(110)		(67.1%)
*No postmenopausal bleeding		330		86.9%*
MENORRHAGIA PRIOR to CESSATION	104		19.1%	
(Complaint: postmenopausal bleeding)		(54)		(32.9%)
*No postmenopausal bleeding		50		13.1%*
TOTAL NUMBER POSTMENOPAUSAL CASES	816	816	100%	

Data were recorded on a total of 816 patients past the menopause, but of this number the histories of 272 have been disregarded for the reasons indicated in Table 5. Among 544 women

interviewed a year or more after spontaneous cessation of their periods, 440, or 80.9 per cent, gave a history of gradual or abrupt cessation of bleeding with no occurrence of menorrhagia. This figure suggests that 19 women of every 100 going through the menopause experience increased bleeding prior to cessation of their flow.

However, among women over 40 who consult a gynecologist we might expect to find a higher incidence of menorrhagia than occurs among the population at large. For that reason we believe a more reliable figure has been obtained from the histories of a somewhat smaller group of women. Three hundred and eighty, or 70 per cent, of the women who came to the office after their menopause came with no complaint referable to bleeding.

In most instances they came because of relaxation, prolapse, symptoms referable to postmenopausal atrophic changes, breast lesions, and the like. Of that group, only 50, or 13 per cent, had experienced menorrhagia prior to cessation of their periods. This figure, 13 women of every 100, we present as an estimate of the incidence of increased flowing at the time of the menopause.

In the records of the Buffalo General Hospital we have found nothing to suggest a significantly high incidence of adenocarcinoma of the uterus among women whose menstruation continues past the forty-ninth year. In fact, the occurrence of adenocarcinoma of the fundus was frequently noted among younger women. We should be inclined to agree with Taylor's observation[7] that the woman who menstruates regularly in her fifties is less likely to have a malignancy than the woman who experiences postmenstrual flowing in her forties.

Relation of Menorrhagia at Menopause to Postmenopausal Bleeding

It is not the purpose of this report to consider the significance of postmenopausal bleeding. However, the possible significance of one factor in the recurrence of uterine bleeding after the menopause should not be overlooked. We had suspected that the endometrial hyperplasia frequently associated with menorrhagia at the menopause might persist asymptomatically in a uterus destined to bleed again with the postmenopausal development of an adenocarcinoma in the fundus.

Since it is practically impossible to say when the individual past the menopause is beyond the probability of further uterine pathology, only an estimate can be made, in a series of this size, as to the predisposition of a group to develop postmenopausal bleeding. However, considering the data in Table 5, it is interesting that among 164 women noting a recurrence of vaginal bleeding one or more years after cessation of their periods, 54, or 32.9 per cent, gave a history of heavier flowing during their menopause. In this group, the incidence of menorrhagia preceding cessation of the flow was nearly three times greater than that experienced by the women who came in with no history of postmenopausal bleeding.

This figure would suggest that the woman who apparently spontaneously recovers after menorrhagia at the menopause runs a much greater chance of developing postmenopausal bleeding than the woman who experienced an abrupt or gradual cessation of her flow. If menorrhagia at the menopause predisposes the individual woman to a higher incidence of postmenopausal bleeding, women who experience increased flowing prior to cessation of their periods might be expected to develop a higher incidence of malignancy of the fundus during their postmenopausal years. However, as indicated in Table 6, we found no evidence that the incidence of carcinoma of the uterus was higher among women who had noted menorrhagia at the menopause than among women who had experienced an abrupt or gradual cessation of their flow. Undoubtedly we should consider menorrhagia prior to the menopause as one problem and postmenopausal bleeding as another, but the possibility of the former predisposing the individual to the latter might well be kept in mind.

TABLE 6

INCIDENCE of MALIGNANCY as the CAUSE of POSTMENOPAUSAL BLEEDING
164 women after the menopause

TYPE of MENOPAUSE	NO. of WOMEN	INCIDENCE of MALIGNANCY
MENORRHAGIA PRIOR to CESSATION	54	39.3 %
GRADUAL or ABRUPT CESSATION	110	39.3 %

The figures shown in Table 6 are not in accord with data usually quoted on postmenopausal bleeding. Norris[5] found the reappearance of vaginal bleeding after a year or more of amenorrhea to be due to malignancy in 52.9 per cent of 1,797 cases. Similarly, among 2,000 patients admitted to the hospital on account of postmenopausal bleeding, Keene[3] found the incidence of carcinoma to be 61.4 per cent. However, it should be noted that both Norris and Keene were reporting on the incidence of malignancy as the cause for postmenopausal bleeding among patients entering a hospital for diagnosis and/or treatment.

It is of course possible that carcinoma is not

responsible for the occurrence of postmenopausal bleeding in as high a proportion of the women seen by the practitioner as has been indicated by reports on the incidence of malignancy among patients admitted for hospital care. Among the patients seen in office practice, postmenopausal bleeding may be due to senile vaginitis, vaginal erosion secondary to prolapse, easily removed polyps, or to the excessive use of estrogenic therapy for menopausal symptoms. Such causes for postmenopausal bleeding do not appear frequently among patients referred for hospital care, and their inclusion probably accounts for the relatively low incidence of malignancy noted in Table 6. Our data indicated that 4 of every 10 women who consult the doctor on account of a recurrence of vaginal bleeding a year or more after the menopause have a malignant tumor. For that reason alone—particularly if menorrhagia at the menopause predisposes the individual to postmenopausal bleeding—our measures to control menorrhagia prior to the menopause might well take into account the desirability of insuring against the occurrence of later pathology in the uterus.

Discussion

It has been evident for thirty years that an early diagnosis and the prompt institution of adequate treatment provide the only means of saving the lives of women with a malignancy beginning in the cervix or uterine fundus. Professional groups and lay audiences are repeatedly warned of the possible seriousness of irregular or increased vaginal bleeding in women over 40 years of age.

Yet personal experience too often modifies the individual's apprehension regarding excessive bleeding at this time of life. Not infrequently a woman experiencing menorrhagia at the menopause recovers after the annoyance of a few prolonged or profuse periods. Thereafter she is convinced of the harmlessness of the heavy or irregular flowing she experienced at the change of life, and in this way a doctrine of complacency may be perpetuated from one generation to the next. It is this very complacency which constitutes our major problem.

We recognize that only a small proportion of the individuals with suggestive bleeding are destined to develop fatal pathology. To enlist the interest of the fortunate majority we must frequently remind them that the unfortunate minority exists unrecognized among their number. To convince ourselves of the wisdom of this policy it is well occasionally to question the significance of menorrhagia at the menopause. However, whenever we do so, we find the incidence of uterine malignancy as a cause of increased bleeding a threat to each woman in this age group until adequate measures to eliminate the presence of carcinoma have been employed by her physician.

Summary

According to the data presented, at the time of the menopause 87 per cent of women experience a gradual or abrupt cessation of their menstrual flow, and in only 13 per cent the flow is increased prior to cessation of the periods.

Fibroids of the uterus were responsible for one-half the instances of increased bleeding in women over 40.

Malignancy of the uterus was the cause of increased bleeding prior to the menopause in 5.3 per cent of patients.

When uteri not containing fibroids were curetted in order to explain menorrhagia occurring before the menopause, the incidence of adenocarcinoma in the fundus was 9.1 per cent.

It is suggested that women who experienced menorrhagia prior to the cessation of their periods are more likely to develop postmenopausal bleeding than women whose menopause is characterized by an abrupt or gradual cessation in the menstrual flow. The significance of this observation is suggested by the incidence of malignancy as a cause for postmenopausal bleeding.

Conclusion

Data are offered in support of a frequently emphasized dictum—whenever women over 40 develop increased menstrual bleeding, no other diagnosis should be accepted until the possibility of a malignancy in the uterus has been eliminated.*

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the October 1 issue and will concern "Treatment of Poisoning by the Barbiturates."

Carbon Monoxide Poisoning

DR. EUGENE F. DUBOIS: Carbon monoxide poisoning is not the invention of the gas companies and the automobile manufacturers. It probably started as soon as man began making fires in closed spaces. It is with us frequently in this city. I want to emphasize the fact that it does not always come with the label, that it does not always come with the smell of illuminating gas, and that many cases are undiagnosed.

We saw carbon monoxide poisoning very frequently at Bellevue Hospital. It still is frequently seen there, I understand, but not so frequently as it used to be. It was a common sight to see on the ward the men from the gas company working most efficiently as a team on the patients who were brought in by the ambulance or the gas company as victims of carbon monoxide poisoning.

Today Dr. Milton Helpern is going to discuss the occurrence and pathology of carbon monoxide poisoning.

DR. MILTON HELPERN: As Dr. DuBois has indicated, carbon monoxide poisoning is one of the most ancient forms of poisoning and dates back to the first use of fire. The incomplete combustion of any type of fuel—gaseous, liquid, or solid—is accompanied by the evolution of carbon monoxide, and proper provision for its escape during fuel combustion is most important in preventing asphyxial poisoning.

In actual experience, most cases of carbon monoxide poisoning result from the inhalation of uncombusted illuminating gas which contains a high percentage of carbon monoxide. In such cases, it is even customary to certify the cause of death as illuminating gas poisoning. As already mentioned, carbon monoxide is generated during any conflagration and during the incomplete combustion of any type of fuel, including natural gas, which does not contain carbon monoxide as an ingredient. Formerly, when heating appliances were not so efficiently constructed as they are now, we saw many cases of carbon monoxide poisoning which occurred when the gas or other fuel was incompletely combusted and the liberated carbon monoxide was allowed to accumulate in a relatively confined space.

Another important source of carbon monoxide is the exhaust gas of the internal combustion automobile engine, which contains a very high percentage—about 7 per cent—of carbon monoxide. If this automobile exhaust gas is inhaled for a short length of time—for example, in a small closed garage—fatal poisoning will occur rapidly.

I should like to point out the incidence of fatal carbon monoxide poisoning in New York City by means of the statistical tables in the 1939 "Annual Report of the Office of the Chief Medical Examiner." In 1939, there were 1,210 suicides, 445 of which were by inhalation of illuminating gas and 31 by inhalation of motor exhaust fumes. From year to year the suicide total is about the same. The total of 476 deaths from carbon monoxide poisoning represents a large per cent of all the fatal suicidal poisonings encountered.

In the table of accidental deaths by poisoning, which includes a certain number of cases in which the circumstances could not be determined and which were probably not all accidental, there was a total of 971 deaths, including 440 deaths from acute and chronic alcoholism and 153 deaths during anesthesia. One hundred and seventy-two of these were carbon monoxide poisonings resulting from the inhalation of illuminating gas and 47 from the inhalation of carbon monoxide, the origin of which was other than illuminating gas. In the latter group, the source of the gas was automobile exhaust fumes or "coal gas" escaping from defective furnace flues. The total number of accidental and undetermined deaths from carbon monoxide poisoning was 216 in 1939.

The incidence of accidental carbon monoxide poisonings has dropped considerably. Fifteen years ago, there were more than 800 fatal accidental poisonings in a year. Most of these resulted from the use of defective gas fixtures.

Since gas lighting appliances in the home have been largely replaced by those using electricity, there has been a tremendous diminution in the number of potentially dangerous gas outlets and fixtures. Gas stoves and heating appliances are also tested much more rigidly before they are allowed to be used by the public. Most of the accidental carbon monoxide poisonings we now see occur when a senile arteriosclerotic individual or an intoxicated person puts a pot on the stove, turns on the gas, but forgets to light it. Occasionally a person trips over and separates the rubber connecting hose between the gas outlet on the wall and a portable gas stove or burner. Then there are many instances in which a connecting rubber gas hose is old or brittle or otherwise defective so that sufficient gas leaks from it to cause asphyxiation. One should remember that the incidence of accidental carbon monoxide asphyxiation is seasonal; it occurs most frequently during the winter months when fuel consumption is heaviest.

One sometimes hears a curious and erroneous explanation of the cause of fatalities when persons are found dead of carbon monoxide poisoning in closed, unventilated rooms heated by open gas burners. The newspapers occasionally carry a story that the burner extinguished itself after the oxygen in the room was all used up, after which the escaping gas poisoned the occupants. Obviously, such an explanation is fallacious. The oxygen supply is not used up in that way. The occupant is poisoned by the carbon monoxide escaping from the burner while it is lighted because of faulty, incomplete combustion of the gas, or because the gas was turned on and the burner not lighted in the first place.

I should like also to emphasize a fact that Dr. DuBois has already mentioned—that not all cases of carbon monoxide poisoning are labeled as such when they first come under observation. It is true that in the majority of cases the diagnosis is very simple. The scene makes the case an obvious one. The victim is found dead or unconscious in an atmosphere of carbon monoxide. There may have been careful, detailed preparations for suicide. The cracks around the doors and windows and the keyholes are sealed by being covered over or stuffed with paper or rags; the victim is unconscious or dead on the floor in front of the stove with all the petcocks turned on and blowing gas. Frequently there is a suicide note.

It is important to remember that there are cases, usually accidental, in which the scene is misleading because the source of the carbon monoxide is not apparent. In such cases, the victim may be found semistuporous or unconscious and brought to the hospital with an erroneous diagnosis. Mild cases of poisoning with misleading symptoms of headache, nausea, and vomiting are misdiagnosed as gastroenteritis or food poisoning, especially when several persons become ill with such symptoms after having partaken of a meal. They may recover spontaneously and be discharged from the hospital without a correct diagnosis of carbon monoxide poisoning ever having been made. In other cases the patient is admitted to the hospital in coma and, because a source of carbon monoxide or its presence was not detected or suspected at the scene where the individual was found, the correct diagnosis is not made or even considered. The patient dies in coma after several hours or days. If the victim has survived several hours, much of the carbon monoxide will have been eliminated and an autopsy may reveal little to prove carbon monoxide poisoning. If blood was not taken for qualitative and quantitative determinations of its carbon monoxide content, the diagnosis will not be made. If such a patient survives for almost twenty-four hours, the gas will have been completely eliminated and brain lesion may not have had sufficient time to develop, so that the case cannot be diagnosed, not even at autopsy. Fortunately, in patients who survive more than twenty-four hours in coma, the postmortem findings in the brain are fairly characteristic.

In fatal cases, the pathologic lesions vary with the type of case. When asphyxiation by carbon monoxide occurs rapidly from the inhalation of a high concentration of the gas, as in the case of suicides who turn on several gas petcocks in a closed room, the necropsy will reveal the characteristic cherry-red carboxyhemoglobin coloration of the skin, blood, and congested organs.

The pinkish-red color of the suggillations immediately suggests the diagnosis even before the body is opened. In such cases the blood will give strongly positive qualitative tests for carbon monoxide and the quantitative tests will reveal a high percentage of saturation of the blood with carbon monoxide. The postmortem diagnosis in cases of acute, fatal carbon monoxide asphyxiation is obvious to the experienced observer.

Kodachrome transparencies will illustrate the characteristic cherry-red color of the postmortem suggillations in a case of acute carbon monoxide poisoning in which the individual is found dead in the atmosphere of the gas. As the blood gravitates into the vessels of the dependent portions of the body after death, the cherry-red color becomes quite intense. In a similar colored photograph, the body of a man who died of acute alcoholism shows the ordinary purplish-blue postmortem lividity.

The situations in carbon monoxide poisoning

are sometimes very strange, as illustrated by the following case.

The deceased, a middle-aged white man, went down into the basement of his house to commit suicide. He tried to cut his throat, but not very effectively. There were multiple hesitation cuts on the side of the neck which only penetrated the skin. After that he attempted to stab himself several times through the frontal portion of the scalp, but the thickness and hardness of his skull stopped the knife. In disgust, he removed the belt from his trousers, looped it around his neck, and fastened the other end to an overhead pipe in order to hang himself; but the weight of his body caused the belt to snap and he came crashing down. In falling, his head struck and broke off a gas jet protruding from the wall; the escaping gas caused his death. The carbon monoxide saturation of his blood was 70 per cent, and the intense cherry-red postmortem lividity was striking. It was a case of incidental, if not accidental, carbon monoxide poisoning complicating several unsuccessful attempts at suicide by other methods.

There are occasional cases in which the victim is also found dead, but in which the asphyxiation was more prolonged in the atmosphere of the gas. In such cases, in addition to the cherry-red carboxyhemoglobin coloration of the congested organs, one may find numerous fine petechial hemorrhages throughout the white matter of the brain. These petechial hemorrhages are not seen in the rapidly fatal asphyxiations, which show only the characteristic cherry-red or rose-colored lividity.

If the individual survives and is removed from the atmosphere of the gas into the fresh air, the carbon monoxide is eliminated fairly rapidly from the blood into the expired air and the blood returns to normal. Unless a sample of blood is taken within a very short time of the removal of the victim from the atmosphere of the gas, the tests for carbon monoxide will not reveal the highest per cent of carboxyhemoglobin and, if too long a time elapses before the blood is withdrawn, no carbon monoxide may be found. In twenty-four hours, the asphyxiated person will have eliminated all of the gas. The gas is eliminated more rapidly when resuscitation measures have been carried out.

Bodies of persons who succumb after twenty-four hours will no longer show the cherry-red coloration. The carboxyhemoglobin will have already disappeared, and the color will not differ from that of an ordinary dead body.

But there is another lesion which appears just about this time, after about twenty-four hours or more of survival in coma. In such delayed deaths, one finds in the brain characteristic bilateral symmetric softening or anemic necrosis of the globus pallidus, a lesion which was called attention to by Kolisko a long time ago. As the period of survival in coma after asphyxiation increases, this lesion becomes more conspicuous. The anterior third or half of the globus pallidus appears crumbly in texture and is sequestrated from the surrounding tissue. The consistency and appearance, except for the color, is very much like that of deviled egg. In most cases, the necrotic tissue is anemic in appearance; in some cases, it may be slightly infiltrated with blood. There may be—but in most cases there are not—associated petechiae in the cerebral white matter.

I have several specimens of brain which demonstrate the symmetric anemic necrosis of the globus pallidus in delayed deaths from carbon monoxide poisoning. Despite the statement in many textbooks, the occurrence of petechial hemorrhages in the cerebral white matter in addition to the anemic softening of the globus pallidus in delayed deaths is infrequent. Petechial hemorrhages in the white matter of the brain have already been mentioned in cases of prolonged acute, fatal asphyxiation in the atmosphere of carbon monoxide.

In delayed deaths and in some prolonged acute fatal cases, one occasionally finds lesions in other organs in addition to the brain lesions. There may be hemorrhages in the heart muscle, but these are not very commonly encountered. Subendocardial hemorrhages and mural thromboses may occur in the ventricles. Scattered trophic blisters or bullae may develop in the skin. The appearance of bullae may be a useful clue in the diagnosis of an obscure case of unconsciousness caused by carbon monoxide asphyxiation in which there are also hyperactive and abnormal deep reflexes suggestive of bilateral pyramidal tract disease. The possibility of carbon monoxide poisoning should always be considered in such a case.

Aside from the lesions in the brain, in the heart, and in the skin, there are no other characteristic lesions in delayed deaths. Pulmonary edema and a hypostatic bronchopneumonia are the immediate cause of death in patients who survive several days. I should like to emphasize the fact that the only consistent finding in delayed deaths from carbon monoxide poisoning is the bilateral anemic necrosis of the globus pallidus, which probably has its inception during the period of anoxemia occurring at the time of the asphyxiation and during the initial period of unconsciousness when the concentration of carbon monoxide in the blood is greatest. The lesion is not altogether restricted to carbon monoxide poisoning. It occurs rarely in other conditions.

We have seen it twice now in cases of severe barbiturate poisoning, when the patient has remained unconscious for a long period of time. A third such case has recently been reported in the literature.

DR. DUBOIS: Dr. Cattell will discuss the pharmacology and treatment of carbon monoxide poisoning.

DR. MCKEEN CATTELL: From a physiologic standpoint carbon monoxide is a relatively inert gas. It owes its toxic properties to the fact that it combines with hemoglobin and makes it unavailable for the transport of oxygen. This important discovery goes back to the middle of the last century and Claude Bernard. Every symptom of carbon monoxide poisoning is accounted for by the asphyxia thus produced.

In 1932 Fenn and Cobb reported that in intact frog muscle the metabolism is increased between two and three times when air is replaced by 76 per cent carbon monoxide plus 21 per cent oxygen. In a second paper they extended these observations to other tissues of both cold- and warm-blooded animals and showed that the increased metabolism involved the actual burning of carbon monoxide to carbon dioxide by the consumption of oxygen. This occurs to an appreciable extent only in skeletal and cardiac muscle.

It is hardly probable that oxidation plays an appreciable role in the elimination of carbon monoxide in the intact animal or man, since by comparison the tissue concentration is very low indeed.

The circumstances that govern the combination of oxygen and carbon monoxide with hemoglobin form the basis for the treatment of carbon monoxide poisoning. It was shown by Haldane that the relative amounts of oxyhemoglobin and carboxyhemoglobin existing in the blood are proportional to the partial pressure of each gas. Thus, a reversible equilibrium exists which conforms to the laws of mass action. However, since the affinity of carbon monoxide for hemoglobin is much greater than that of oxygen, comparatively small amounts result in a significant percentage of carboxyhemoglobin. A number of investigators have studied the relative combining power for various concentrations of the gases. Carbon monoxide in a concentration of 0.1 per cent in air (20.9 per cent oxygen) results in equal parts of oxyhemoglobin and carboxyhemoglobin. From such experiments it can be calculated that the affinity of carbon monoxide for hemoglobin is 210 times that of oxygen. It follows that if the amount of oxygen in the inspired air is doubled in the presence of the same amount of carbon monoxide, the percentage of carboxyhemoglobin will be 25. This points the way to the most important aspect of treatment —the administration of oxygen in high concentrations. This is done through a face mask with artificial respiration if necessary.

There is another point that should not be forgotten in connection with oxygen therapy—its value in preventing asphyxia. No time should be lost in improving the oxygen supply to the tissues, and by giving oxygen, an appreciable extra amount over that obtaining with atmospheric air is transported in combination with hemoglobin. Furthermore, the quantity dissolved in the plasma is also increased.

Dr. Maurer in Dr. Drinker's laboratory has studied the effect of carbon monoxide poisoning on the production of lymph in dogs. Using 0.5 per cent carbon monoxide he showed that the lymph production begins to increase when the average oxygen saturation of the blood is reduced to 61 per cent, which conforms closely to the results obtained by the author during the respiration of air that was deficient in oxygen. The average increase of flow was two and one-half times after thirty minutes' exposure to the carbon monoxide which resulted in a high concentration of carboxyhemoglobin, averaging 87 per cent. Treatment with 100 per cent oxygen restored the blood gases to normal and resulted in decrease in lymph production.

These observations remind us of the story in secondary shock, and it would seem that capillary damage should result in the syndrome of secondary shock. As a matter of fact, evidence of cerebral and pulmonary edema has been reported. I should like to ask those who have seen cases of carbon monoxide poisoning whether or not they exhibit evidence of peripheral vascular failure.

Of all the conditions in which carbon dioxide is administered there is none having better indications than carbon monoxide poisoning, for not only does it act as a respiratory stimulus but it also promotes the dissociation of carboxyhemoglobin and oxyhemoglobin. In the early stages of poisoning hyperpnea may be present, but the later stages are always attended by respiratory depression. Henderson, who introduced the carbon dioxide treatment, believed that the carbon dioxide concentration was depleted because of the hyperpnea occurring in the initial stages and because of a depressed metabolism. That the carbon dioxide concentration should be low under these circumstances hardly makes sense, and the point has been re-examined by Dill and his associates at the Fatigue Laboratory at Cambridge. In a recent issue of the *American Journal of Physiology* they describe the circulatory and respiratory responses to carbon monoxide poisoning in dogs and man. Carbon monoxide was administered slowly until carboxyhemoglobin reached 40 to 50 per cent.

Plasma carbon dioxide first fell and then increased with a shift of the pH toward the acid side. In the face of this no hyperpnea occurred, so it was concluded that carbon monoxide, or rather the anoxia, results in a depression of the respiratory center.

At first sight the depression of the center caused by carbon monoxide asphyxia seems to *run counter to the well-known influence of oxygen* lack in stimulating the respiration. However, this contradiction is resolved when we take into consideration the experiments of Schmidt and Comroe, showing that respiratory stimulation by oxygen lack is mediated through the carotid sinus. In carbon monoxide poisoning the oxygen dissolved in the plasma of the arterial blood is not diminished, and since this is the oxygen to which the carotid sinus responds, the carotid sinus reflex is not brought into action, and thus the direct depressant effect of asphyxia on the respiratory center is unmasked.

This evidence does not speak against the use of carbon dioxide in carbon monoxide poisoning; on the contrary, the depressed center may be stimulated by the higher concentration and thus the elimination of carbon monoxide is promoted. Moreover, the increased carbon dioxide facilitates the release of oxygen to the tissues and the dissociation of carboxyhemoglobin.

For many years 5 per cent carbon dioxide was employed, but on the basis of Dr. Drinker's studies 7 per cent carbon dioxide in 93 per cent oxygen is now generally recommended.

Briefly, to summarize the steps that are useful in the treatment, the first thing to think of is to remove the patient to fresh air, and the second is to institute artificial respiration when necessary, while at the same time carbon dioxide and oxygen should be administered.

It has been shown that by these means the elimination of carbon monoxide will be so hastened that it is practically all lost from the body within twenty minutes to half an hour, whereas without them it would take approximately two hours to accomplish the same thing. The fourth consideration is the application of measures to combat shock.

With regard to drug therapy I need to say little. That may be left to the informal discussion, but in the light of the condition with which we are dealing it is obvious that drug therapy has very little place.

In the urge to do something, a variety of stimulants are commonly injected by the hypodermic route, and these include strychnine, caffeine, camphorated oil, atropine, digitalis, epinephrine, pituitary extract, alpha-lobeline, methylene blue, and many others. Of this list I think caffeine is perhaps the only one that deserves serious consideration.

Caffeine has some reputation as a respiratory stimulant, but we all know that it is none too effective in conditions of respiratory depression. However, it appears to be relatively harmless and in moderate doses may be helpful. In this condition it is administered intravenously.

DR. DUBOIS: Dr. Helpern, have you some more remarks you would like to make?

DR. HELPERN: There is another hazard that arises when a person commits suicide by inhaling illuminating gas. The gas when mixed with air in proper concentration is highly explosive. There have been a number of cases recently in which destructive explosions have been set off in the gas-filled premises, the gas having been liberated from the kitchen range by a person intent on suicide. In such cases a lethal amount of gas has been inhaled by the victim before the explosive concentration of the gas is attained. The explosion occurs when the mixture of gas and air is ignited either by an electric spark or by a pilot light which has been left burning on the stove or under the refrigerator. At times it is difficult if not impossible to determine the source of ignition. In any case a destructive explosion of illuminating gas occurs, with considerable damage to the premises. The body of the deceased may be scorched by the blast. In all such cases the cause of death was carbon monoxide poisoning which was readily proved by the high concentration of carbon monoxide in the blood of the deceased. Despite the obvious cause of death in such cases in which destructive explosions of the gas have subsequently occurred, unwarranted law suits for damages or for accidental death benefits have been instituted by the relatives of the deceased, who refuse to accept the verdict of suicide clearly indicated by investigation of the circumstances and by the cause of death. In one interesting case in which an explosion occurred after a successful gas suicide attempt, the force of the explosion was so great that it blew out all the walls in the apartment and piled up most of the furniture on the outdoor terrace. The place was a shambles. The kitchen stove, which was the source of the gas, was blown away and demolished so that it was impossible at first to know how many petcocks were turned on. This was subsequently determined by the position of the flanges in the feed pipe of the stove, which indicated that four burners of the stove had been turned on full. A police detective painstakingly combed through the rubble in the wrecked apartment and found the many small fragments of a note written by the deceased which clinched the case as a suicide. The explosion of illuminating gas that has

permeated throughout an entire lower floor of a building not of steel construction might very well result in the collapse of the building and in the death and injury of many of the occupants.

DR. DUBOIS: The session is now open for discussion. I am sure Dr. Helpern and Dr. Cattell will be glad to answer questions.

DR. OSCAR BODANSKY: To what extent are clinical symptoms obtained by people who work in atmospheres where there is carbon monoxide in nonlethal doses? I mean, for example, people at busy traffic corners or workers in a garage.

DR. CATTELL: There have been reports indicating the possible importance of chronic poisoning; I have in mind particularly the study of Beck, who claims that the continued inhalation of very small amounts of carbon monoxide results in definite lesions in the central nervous system, with disturbance of function.

There is some doubt regarding the significance of these studies. By their nature, adequate controls are difficult to get and there is some question as to whether the symptoms are truly representative of carbon monoxide poisoning. Perhaps Dr. Helpern will say something about that.

DR. HELPERN: Most healthy persons with less than 18 or 20 per cent carbon monoxide saturation of the blood are symptom-free or present only mild symptoms, depending upon whether they are at rest or exercising. Headache is usually the first symptom complained of. Dangerous concentrations of carbon monoxide may accumulate rapidly in small unventilated private garages, since automobile exhaust contains about 7 per cent of carbon monoxide. In large public garages, the hazard of fatal acute poisoning does not exist, although many such garages show a carbon monoxide concentration of more than 0.01 per cent or 1 part in 10,000. Such a concentration of carbon monoxide might cause mild symptoms of intoxication, such as headache, if a worker were continuously exposed to it for several hours. Most of the reports dealing with the concentration of carbon monoxide in street air, especially at busy traffic intersections, give values far below 0.01 per cent, although concentrations as high as 0.04 per cent have been reported for brief intervals. The amount of carbon monoxide in street air is not considered a health hazard. The traffic policeman is probably the only one who is exposed sufficiently long to concentrations of carbon monoxide in street air which might give rise to symptoms.

The question of chronic carbon monoxide poisoning, a condition resulting from the continued or repeated inhalation of small amounts of carbon monoxide, is a puzzling one, and the great variety of conditions attributed to chronic carbon monoxide poisoning include not only disorders of the central nervous system and the organs of special sense, but also of the circulatory system, the digestive system, and, in fact, of almost every system in the body. There is sufficient pathologic evidence for us to attribute certain disabilities, especially those referable to the central nervous system, to the delayed effect of an acute carbon monoxide asphyxiation in which a sufficient amount of gas was inhaled at one time to produce a high percentage of carbon monoxide saturation of the blood with resultant anoxemia and irreversible damage to the tissues. Although nonfatal severe acute asphyxiations by carbon monoxide are fairly common, sequelae are comparatively rare.

It is important not to confuse the sequelae of an acute nonfatal carbon monoxide asphyxiation with what has been designated as chronic carbon monoxide poisoning supposedly resulting from the repeated inhalation of small amounts of the gas. With this caution in mind, a critical examination of cases of so-called chronic carbon monoxide poisoning does not reveal much satisfactory evidence for the existence of such a condition, or that various permanent or transitory neurologic and circulatory disorders are an expression of it or result from it. There is little or no objective evidence, for example, of quantitative measurements of the concentration of the carbon monoxide allegedly inhaled, or measurements of the percentage saturation of carbon monoxide in the blood of the victim during the time of supposed exposure to the gas. The difficulty and impossibility of obtaining such information months or years later are appreciated. In many of the cases of chronic carbon monoxide poisoning reported in the literature, the symptoms and signs described could just as well have resulted from natural disease processes or from other causes.

I have in mind the case of a middle-aged man who was suffering from partial blindness occasioned by retrobulbar neuritis. Several years before this man had worked in a large garage. There were no complaints or episodes of asphyxiation or unconsciousness at the time of his employment. Years later during an admission to one hospital because of his failing vision, a pansinusitis was diagnosed, and arsenic was recovered from his urine. At the time of his discharge from the hospital the optic neuritis was considered to have been caused either by arsenic or by the sinusitis. Carbon monoxide as an etiologic factor did not enter into the picture at that time, but only after hospitalization in another institution was the history obtained that he had been employed in the large garage a long time

before. There was no evidence to show that any dangerous concentration of carbon monoxide ever existed in the garage when the patient worked there or that he ever had any carbon monoxide in his blood at that time. Despite the fact that arsenic was found in his system and that he had a well-proved case of pansinusitis either one of which conditions could have caused an optic neuritis and partial blindness, the mere fact that he had once worked in a garage was sufficient to permit testimony by a medical expert that the patient's visual disturbance was a manifestation of chronic carbon monoxide poisoning and, moreover, that it could not have been caused by arsenic poisoning or by a pansinusitis.

It is true that persons working in poorly ventilated garages and traffic policeman assigned to heavily traveled streets may accumulate concentrations of carbon monoxide in their blood as high as 20 per cent or more after prolonged exposure and that they may develop symptoms of malaise, but there is no satisfactory proof that permanent harm results in such cases.

DR. CATTELL: It is difficult to see how, on the basis of simple asphyxia, a concentration of carboxyhemoglobin as low as 20 per cent could cause damage because of the large factor of safety provided through various circulatory readjustments.

DR. DUBOIS: Unless there are other factors coming in, such as a combination of carbon monoxide with anemia or high altitude. In Denver I suppose 20 per cent saturation with carbon monoxide would be very much more serious than it would be here in New York.

Then the question of heart disease or exertion is important. There is an interesting chart, comparing the condition in simple anemia and carbon monoxide poisoning, in Dr. Drinker's book on carbon monoxide asphyxia. It shows a man with a considerable saturation of carbon monoxide in his blood, and with an oxygen-combining capacity equal to that of a man with 40 per cent hemoglobin. He can stand very much less exercise than a man whose deficiency is due to a simple anemia. So there are special circumstances which must be taken into account in patients who have partial saturation with carbon monoxide.

DR. CATTELL: We see comparable changes from anoxia from other causes, which makes it probable that an oxygen deficiency underlies all the symptoms occurring in carbon monoxide poisoning.

DR. DUBOIS: I should like to ask Dr. Helpern why brain lesions are so common in carbon monoxide poisoning and apparently are found very seldom in other cases of anoxias, such as heart disease, anemias, and so on. Is there any explanation?

DR. HELPERN: I do not know, Dr. DuBois, what the explanation is, except to say that it may depend upon the difference between the oxygen dissociation curves of the blood in carbon monoxide poisoning and in a severe anemia where there has been a comparable reduction of oxygen carrying capacity. This was pointed out in 1925 by Stadie and Martin whose paper is quoted by Dr. Drinker in his book on carbon monoxide poisoning. They show that the blood of an anemic person has a normal type of oxygen dissociation curve with sufficient oxygen tension, despite reduced oxygen-carrying capacity, to supply additional oxygen to the tissues when needed, but that the blood in carbon monoxide poisoning has an abnormal type of oxygen-dissociation curve with such marked lowering of the oxygen tension as to be unable to supply additional oxygen to the tissues on sudden demand, despite the fact that the blood still contains several times the amount of oxygen necessary for tissue function. The anemic person therefore has a more flexible mechanism with which to supply oxygen to the tissues than the person who is suffering from carbon monoxide poisoning.

This difference in the anoxemia of carbon monoxide poisoning as contrasted with that of severe anemia may possibly explain the production of the brain lesions in the former condition and their absence in the latter.

It is interesting that these symmetrical softenings in the globus pallidus have never been observed or produced experimentally in the lower animals. The lesion is peculiar to human beings. Why this is has never been explained.

DR. EPHRAIM SHORR: Is not the problem one of what happens to the tissues in carbon monoxide poisoning—that is, an impairment of the affinity of the iron system in the tissues—so that there is a failure of utilization as well as the failure of deficiency? In ordinary anemias and anoxia from other causes there are no disturbances in the transfer of oxygen in the cellular oxidation.

DR. DUBOIS: Do you want to comment on that, Dr. Cattell?

DR. CATTELL: It is known that very high concentrations of carbon monoxide—that is, several atmospheres—do interfere with the respiratory enzymes, as was shown by Warburg. In the body one is ordinarily dealing with concentrations of carbon monoxide which are of the order of a fraction of 1 per cent, and I think it has never been demonstrated that such amounts have any influence on living systems.

The fact that mice can survive indefinitely in an atmosphere of carbon monoxide, if sufficient

oxygen is provided, would indicate that there is no respiratory interference.

DR. SHORR: It would be interesting to know how brain oxidations are influenced under those circumstances.

DR. HARRY GOLD: Are mice especially resistant to poisoning by carbon monoxide? Dogs cannot live more than thirty minutes in a concentration of 1.5 per cent in ordinary air.

DR. CATTELL: Probably not. The point is that if one provides a sufficiently high concentration of oxygen there will be enough carried in the plasma to sustain life. Haldane calculated that this would be provided by three atmospheres of oxygen, and he reasoned that if the toxic effects of carbon monoxide were confined to its influence on hemoglobin, the mice should survive an added atmosphere of carbon monoxide. He put the matter to the test and showed that mice survived indefinitely in a mixture of 25 per cent carbon monoxide and 75 per cent oxygen at 4 atmospheres pressure.

DR. GOLD: I want to ask Dr. Helpern whether carbon monoxide is lost rapidly after death so that one must examine the body at once?

DR. HELPERN: No. There is no appreciable loss of carbon monoxide from the body after death. It can be detected in the blood of decomposed bodies and in the blood clots obtained from exhumed embalmed bodies months after burial.

It is important, however, to remember that carbon monoxide disappears rapidly from the living body after the victim is removed from the atmosphere of the gas into the fresh air. The gas is eliminated even more rapidly if the inhalator is used. If an accurate determination is to be made of the maximum concentration of carbon monoxide in the victim's blood, about 20 cc. of blood should be withdrawn from a vein immediately or as soon as possible after exposure, and placed in a small tightly stoppered bottle to which a small amount of citrate has been added. When the concentration of the carbon monoxide in the blood is high, the blood usually remains fluid and the addition of citrate is unnecessary. Medicolegal questions frequently arise in connection with victims of carbon monoxide poisoning who recover or survive long enough for the gas to have disappeared from the blood. Failure to remove blood for chemical tests may leave questionable the diagnosis of an authentic case. The qualitative tests can be carried out at the bedside. A drop of blood is diluted with 10 cc. of water in a test tube and a few drops of 10 per cent sodium hydroxide are added. Diluted normal blood which should be used as a control turns brown; diluted blood containing carbon monoxide remains pink after the addition of the alkali. The qualitative tests will not show the presence of carbon monoxide if the blood is less than 10 per cent saturated with the gas.

DR. KIRBY MARTIN: I think there may be misunderstanding about the value of the Henderson-Haldane treatment, because our understanding of the mechanism has changed. There is one, and only one, means of treatment of carbon monoxide poisoning at the present time, and that is a mixture of carbon dioxide and oxygen which makes the patient ventilate faster and speeds the elimination of carbon monoxide from the blood.

When I was working experimentally on dogs with Stadie, we found a shift in the oxygen dissociation curve in the presence of carbon dioxide and a relatively high tension of the oxygen in the tissues. Thus, the explanation of the efficiency of carbon dioxide has been changed, but the treatment remains exactly as it was when Henderson described it in 1932.

DR. GOLD: Dr. Helpern says that exhaust gas contains about 7 per cent of carbon monoxide. I wonder whether most people know that the gas from the smoking of cigars contains about 7 per cent of carbon monoxide, and about 4 or 5 per cent from these little things (holding up a cigarette).

DR. MARTIN: May I say something about a cigarette? About ten years ago there was an expedition to high altitudes by someone whose name I cannot recall. He was not a scientist but was doing it purely for sport. He wrote up his experiences. When he and his party got to a high altitude where three or four steps would lead to exhaustion, they found that if they would smoke a cigarette and inhale it completely—that is, as deeply as they could—they could go approximately twice the distance with the same amount of exertion or less. That fits in with what I told you a minute ago. It changes the oxygen dissociation curve to a point where they get more oxygen at a lower tension. A cigarette does help in that respect.

DR. GOLD: It is the carbon monoxide that does that?

DR. MARTIN: Yes.

DR. DUBOIS: That is very interesting.

In closing, I want to call attention to the use of canaries and mice in the prevention of carbon monoxide poisoning, a cheap method. At the present time we also have gas masks, and so on, which can be fitted with material to remove carbon monoxide.

Summary

DR. CATTELL: In addition to its presence in artificial illuminating gas, carbon monoxide is formed whenever organic material is burned. It is thus universally present and is one of the

commonest forms of accidental and suicidal poisoning. The source of the carbon monoxide may not be evident, in which case the diagnosis is likely to be overlooked. After survival for several hours most of the carbon monoxide is eliminated from the body, and the symptoms are likely to be misleading.

In rapidly fatal cases, such as may occur from the inhalation of illuminating gas or the exhaust gases from an automobile, there is a characteristic cherry-red discoloration of the skin, blood, and organs. When asphyxiation is more prolonged, numerous fine petechial hemorrhages are frequently found throughout the white matter of the brain. In patients surviving carbon monoxide poisoning for twenty-four hours or more a characteristic lesion occurs in the brain, a bilateral symmetrical softening or anemic necrosis of the globus pallidus. In delayed deaths this is the only consistent finding, although lesions in other organs may be occasionally found.

The question of chronic poisoning has been discussed and the view expressed that there is no satisfactory evidence of such a condition, nor does it appear rational, in view of the large margin of safety of the circulation, that asphyxial damage should occur when the carboxyhemoglobin is present in amounts no greater than from 20 to 30 per cent.

From a pharmacologic standpoint carbon monoxide is practically inert. It owes its toxic properties to the fact that it combines with hemoglobin, thus making it unavailable for the transport of oxygen. Every symptom of poisoning can be accounted for by the asphyxia thus produced. A reversible equilibrium exists in the blood between the proportions of oxy- and carboxyhemoglobin on one hand, and the partial pressures of oxygen and carbon monoxide on the other. But since the affinity of carbon monoxide for hemoglobin is about 210 times that of oxygen, the proportion of carboxyhemoglobin is relatively high.

Treatment consists in the administration of oxygen to promote the elimination of carbon monoxide and to supply oxygen to the tissues. Carbon dioxide is given to stimulate respiration and promote the release of oxygen to the tissues. A mixture of 7 per cent carbon dioxide and 93 per cent oxygen is administered by means of a face mask, with artificial respiration when necessary. With the possible exception of caffeine, drugs have no place in the treatment of poisoning by carbon monoxide. In severe cases measures to combat shock are important.

FOOD FOR OVERSEAS FORCES

The many problems of feeding the overseas troops of the United States are being successfully solved by the Quartermaster's Subsistence Research Laboratory, whose job is to make Army rations palatable and nutritious under adverse conditions of transportation and storage.

Four different types of field rations have been developed, known as Rations A, B, C, and D. Field Ration A is composed of both perishable and nonperishable foods, purchased, in part, in the area where the troops are stationed. In restricted areas troops are given Ration B, which is made up of sugar, salt, flour, and canned or dehydrated meats, fruits, and vegetables.

Where field kitchens can be used, "operational rations" are issued. Ration C, consisting of 6 cans of food, is the chief operational ration. Three of the cans, one for each meal, are identical—containing hard candy, special biscuits, sugar, and soluble coffee. The other three contain meat and beans, meat and vegetables, and meat and vegetable hash. Ration D, an emergency ration, is composed of three 4-ounce chocolate bars, reinforced with thiamine.

Another ration, designed for parachute troops, may replace Ration C. This is called Ration K and includes three moisture-proof and gas-resistant packages, each containing two kinds of biscuit, canned meat or cheese, a confection, a beverage concentrate, chewing gum, and four cigarettes.

DON'T GRUMBLE

If your legs are worn out paying calls—*don't grumble*—you are still walking on American soil.

If your patient gets to his appointment late—*don't grumble*—he may have ridden a bus to your office.

If you are bored with patients who abuse their digestive tracts—*don't grumble*—the O. P. A. will treat them for you.

If you are called out at night—*don't grumble*—picture the horse and buggy and dirt roads.

If the patients flock to you at all hours—*don't grumble*—remember the old days when you almost ran to meet a patient.

If a neurotic calls you on the telephone—*don't grumble*—at least you are saved the ordeal of looking at her.

If your secretary makes a mistake—*don't grumble*—think of the mistakes of yours which she hides.

If you miss your second cup of coffee—*don't grumble*—you had the first cup.

If the income tax hits you a mighty wallop—*don't grumble*—you are still privileged to pay in Uncle Sam's currency.

If you are forced to bed with sickness—*don't grumble*—think of the medicine you would have to take if you were one of your patients.

If you feel so tired you don't think you can last another day—*don't grumble*—Hitler is feeling the same way.—*J. South Carolina M. A.*

Case Report

URTICARIA FOLLOWING A DENTAL SILVER FILLING

HARRY MARKOW, M.D., Brooklyn

WHEN unusual cases of allergy are ultimately diagnosed as to the specific excitant involved, it is generally agreed that a detailed and painstaking history was of paramount importance in the diagnosis. Although the original history may offer no clue as to the cause, repeated questioning of the patient on subsequent visits will often uncover some detail, seemingly unimportant to the patient, which later will prove to be the clue necessary for the diagnosis of the excitant that is responsible for the symptoms.

Sensitivity to, and allergic manifestations from, ingested drugs and chemicals occur frequently and contact dermatitis from metals, especially in industry, is not uncommon. This case is reported not only because it is unusual, but also because a search of the literature fails to reveal any report of sensitivity to mercury or quicksilver when it is in contact with a mucous membrane, with resultant allergic manifestations both locally and in other parts of the body.

Case Report

History.—T. S., a nurse, aged 41, reported to the allergy clinic of the Beth-El Hospital on April 17, 1941, complaining of generalized urticaria since April 2, 1941. The history on admission related that since April 2 she had had daily and nightly attacks of scattered hives on her arms, legs, chest, back, and face which itched intensely. Her description of these lesions was that there suddenly appeared itching red welts of various sizes all over her body and face, associated with a swelling of her lips and tongue and the lining of her mouth. These lesions, which came and went and were a daily and nightly occurrence, were sufficiently severe to interfere with her sleep. However, she continued her duties at the hospital despite her discomfort. She had no idea of the cause of her symptoms. Later, a subsequent and more complete history, which she had not mentioned previously, narrowed the onset of her symptoms to a visit to her dentist, who had filled a cavity in a tooth with a silver filling.

The following morning she experienced her first attack, consisting of scattered urticarial wheals over her arms, legs, chest, abdomen, and face, together with an itching and burning sensation of her body. These symptoms recurred daily and nightly. Three days later she returned and had the filling removed and replaced with a larger filling, and on this visit she noted a burning sensation of the lips, tongue, and lining of her mouth as well as a feeling of rawness and swelling where the instruments came in contact with the lining membranes. On leaving the office she noticed that her tongue and lips were swollen, and later she felt an itching and burning over her body. Scattered hives developed and lasted for several hours. Although she visited the dentist every three or four days, she failed to correlate the hives with the dental work. Since then the urticaria had recurred daily and nightly and the sensation of rawness, burning, and swelling of her tongue and mouth, although less intense, persisted At the time of her admission to the clinic, her symptoms were severe enough to interfere with her sleep, and she felt miserable. There were no changes in her environmental contacts; her diet was unchanged and so was her mode of living.

She had had a mild attack of hives during childhood which was considered, at that time, to be due to foods. A second attack of hives of one week's duration had occurred when she was 21 years old and was in training. That had also been attributed to foods. From October, 1940, to January, 1941, she had had a contact dermatitis of both arms and chest. She was tested by a dermatologist and patch tests revealed a sensitivity to nickel, aluminum chloride, and dress dyes. On advice, she eliminated a deodorant which contained aluminum chloride and avoided black-dyed clothes. She also avoided sharkskin dresses, which irritated her skin. This dermatitis subsided after she had taken weekly x-ray treatments for a period of ten weeks.

A sister of the patient has eczema, and her niece and nephew have hay fever. On physical examination a few small scattered hives were found on her arms, neck, and lower extremities. Her mouth and tongue appeared to be normal although she complained of a sensation of burning, rawness, and swelling of her tongue and cheek on the side of her mouth close to the new tooth filling. A Wassermann test was negative, and urine and blood count were both normal.

Allergy Study.—Intercutaneous tests with foods and inhalants were begun and were continued slowly over a period of two months. These were essentially negative except for an occasional slight reaction to some foods. Eliminating these foods did not influence the appearance or the degree of symptoms during that period.

The patient was asked to obtain from her dentist samples of the ingredients of the silver filling and to bring them to the clinic. These consisted of both metallic mercury, or quicksilver, and metals in powdered form. Amalgam is made by rubbing this metallic powder with small amounts of mercury. The resulting mixture is used and known as an amalgam filling. The metals used in the powder consist of about 60 per cent silver, 10 to 15 per cent tin, and some copper. The amalgam filling contains about 10 per cent mercury or quicksilver. Scratch tests were made with mercury and the powdered metals and resulted in a very light erythema about the site of the mercury test with a negative control. Owing to the physical nature of mercury, a suitable test was a difficult problem. The scratch test was made by rubbing a cotton applicator into the mercury and gently rubbing the

In Treating Secondary Anemia

MAKE THE THERAPY SUIT THE NEED

THE SELECTION of a hematinic for the treatment of secondary anemia must take into account the need for iron—and frequently for vitamins and other factors contained in liver. Whether the patient needs all these substances, or only some of them, the following Squibb hematinics will prove useful.

HEBULON* CAPSULES—because of their content of iron, liver extract and vitamin B Complex, provide factors often simultaneously required by the patient with secondary anemia. Each easy-to-swallow gelatin capsule contains 2 grains exsiccated ferrous sulfate (approx. 40 mg. iron); 50 U. S. P. units of Vitamin B_{12}; and the B Complex Factors present in the liver extract (derived from 16 Gm. fresh liver). Supplied in bottles of 100, 500 and 1000 capsules.

TABLETS FERROUS SULFATE EXSICCATED SQUIBB—where iron alone is indicated. Contain iron in ferrous form—shown in numerous clinical studies to be more effective in smaller dosage than other forms of iron and to have fewer undesirable side-effects. Supplied in 3-grain enteric-coated tablets in bottles of 100 and 1000. Three grains is the U. S. P. dose for exsiccated ferrous sulfate as compared to 5 grains of the hydrated salt. Squibb has always used the exsiccated form.

CAPSULES FERROUS SULFATE WITH B_1 SQUIBB—for prevention and treatment of secondary anemia—in patients with anorexia or other manifestation of Vitamin B_1 deficiency. Each capsule contains 3 grains of ferrous sulfate exsiccated and 1 mg. of thiamine hydrochloride (333 U. S. P. units of Vitamin B_1). Supplied in bottles of 100 and 1000 capsules.

[Continued from page 1648]

scratch site with this. About the area of the scratch test a few discrete hives appeared, but the test itself was only an erythema with a slight linear wheal. The control had a slight linear wheal without an erythema. Since this was not very conclusive, some mercury, spilled into the cupped hand, was rubbed into the skin of the patient's arm. At the same time the opposite arm was rubbed with the clean hand. Within five minutes a diffuse urticarial eruption developed over the area rubbed with the mercury, while the opposite arm remained normal as a control, thus eliminating the probability of an irritable skin. Rubbing the arm with the metal powder did not result in any similar reaction. Similar tests were done on the arms of five other patients, none of whom gave any reaction to either the mercury or the metal powder.

Subsequent Study and Procedure.—These tests with mercury, metal powders, and dry control hand were repeated the following week on the patient and five other control patients with similar results. At our suggestion this filling was removed by the dentist on April 25, 1941. During this procedure the patient again felt the sensation of swelling, burning, and rawness of the mouth and tongue and, within a few hours, she had an intense flare-up of generalized urticaria. Within a week there was a definite relief of all mouth symptoms. Two weeks later these were completely gone, but she still had mild generalized urticaria involving her body but not her face. On May 14, 1941, she reported that the hives were less intense and were becoming milder and that for the first time she had had two days free of symptoms. On this day, another contact test with mercury (rubbed into arm) was immediately followed by a large area of urticaria over the area that was tested. Similar tests on other patients failed to produce any urticarial lesions. Patch tests with bichloride of mercury, tin foil, a gold bar pin, a silver bar pin, and copper earrings were negative. Rubbing the skin with these metal ornaments which she wore also caused no reaction. On May 17, 1941, she reported that she had visited the dentist on two occasions and that the contact of her tongue and cheek with the mirror and other instruments caused a burning sensation of her mouth and tongue and a flare-up of hives the following day. The hives were less intense and were now limited to her arms. Her face was clear, and she was able to sleep. On June 26, 1941, a small amount of mixed mercury filling was prepared by the dentist as if for a tooth filling. Instead, it was supported by her finger against the roof of her mouth for one hour. She immediately noticed a burning sensation on her tongue and a raw feeling in her mouth similar to the original complaints prior to treatment. On the next day, she awoke with a burning sensation of the skin and an outbreak of hives on her arms, thighs, and abdomen, which persisted for about twenty-four hours. Prior to this she had been free of hives for five days, this being the longest such period of freedom of symptoms since the onset of the urticaria.

Examination of her teeth revealed that she had seven other silver fillings in her mouth. It was suggested that these be removed and replaced with cement fillings. Two were removed in the following two weeks and after the removal of each silver filling, there was a flare-up of hives on her body five hours later, lasting for about seven hours. The tongue and mouth were not involved, however, and her sleep was not disturbed. Subsequently, all the metal fillings were removed and replaced with porcelain fillings. On August 6, 1941, her hives ha completely disappeared. On October 2, 1941, sh reported that she was feeling well, was eating a foods, and that the hives had not recurred for th past two months. On March 20, 1942, the patien reported that she has had no recurrence of symp toms since the removal of all the silver fillings in he teeth.

Passive Transfer Experiment.—An attempt to transfer sensitivity to normal skin was made by injecting an area of skin the size of a quarter with the patient's serum in two normal individuals. After seventy-two hours, this area was rubbed with mercury in the same way that urticaria was produced in this patient. These attempts to demonstrate transferred sensitivity to mercury by this method failed.

Discussion

Reference in the literature to sensitivity to mercury, particularly when used in dental fillings, is very uncommon. However, Duke,* in a discussion on fungus allergy, quoted a case of sensitiveness to mercury and amalgam teeth fillings, and the removal of one of the many amalgam fillings was followed by so serious a general reaction to mercury that the patient refused further treatment. He mentioned another case of acne and fungus infection with sensitivity to mercury. There were many mercury fillings in the teeth of the patient, and mercury salts and amalgam filling material reacted on patch test. This patient improved somewhat under treatment with exposures to mercury vapor light, but complete recovery did not occur until injections of sodium thiosulfate had been given. In the case reported here, the onset of urticaria with local buccal and tongue edema and paresthesia followed shortly after the introduction of a mercury filling into a tooth and, repeatedly, exacerbations were induced by the removal of such fillings and by the use of a similar filling placed against the hard palate as a provocative procedure. Although several such fillings were in the mouth for many years, the outbreak of this attack came on only after the last filling. In all probability, sensitivity was induced by contact with the previous fillings, and the allergic response occurred following the last filling. The previous attack of dermatitis due to nickel might suggest that the instruments were the offending factors but subsequent asymptomatic dental work with cement fillings rules out this factor. In addition to the tests cited, compounds of mercury, such as bichloride of mercury and yellow oxide of mercury, were used in patch tests and rub-in tests with negative results.

While this method of demonstrating induced sensitivity to mercury may be unorthodox, the reaction is comparable to those cases which are so exquisitely sensitive to an ingestant, such as egg, that the mere contact of the skin with the excitant results in an immediate allergic reaction such as bronchial asthma, eczema, or angioneurotic edema. Also, it may be compared to the contact test with volatile substances producing a local skin reaction in cases of nasal or bronchial allergic manifestations.

THE OLD VARIABLE DOSAGE

vs.

THE NEW ACCURATE DOSAGE

In the past, Iodides in liquid form were assumed to furnish 1 grain of Potassium Iodide in a drop—but drops vary in size and even the solution might vary as much as 30 grains in an ounce. Today, you can be certain of the correct dosage with ENKIDE (Brewer) 15 grain Enteric Coated tablets of Potassium Iodide.

ENKIDE
(BREWER)
for
IODIDE Administration

ENKIDE is an enteric coated tablet containing 1 gram of Potassium Iodide, U.S.P., that minimizes gastric distress and permits the administration of large doses of Potassium Iodide. Sold on prescription only ($2.25 for a bottle of 100 tablets) Enkide may be prescribed in accurate doses of 1 to 5 tablets a day, in a modern convenient form easy to take.

This case is reported as one of allergy to mercury or quicksilver for the following reasons:

1. Onset immediately following a visit to the dentist when mercury was used in a filling in a tooth.
2. Skin reaction on contact with mercury.
3. Exacerbations (repeated) of symptoms on the removal of mercury fillings from the teeth, with spillovers into the mouth.
4. Complete relief on removal of all silver fillings.
5. Absence of symptoms following dental work which did not involve use of mercury.
6. Allergic background and family history of allergy.
7. Previous history of contact dermatitis, with sensitiveness to nickel, aluminum chloride, and dress dyes.

PERSONAL HYGIENE IS WEAPON AGAINST TROPICAL DISEASE

SOMEWHERE IN THE SOUTH PACIFIC.—The Japs may have withdrawn but the disease axis which makes a bastion of these "tropical paradises" stubbornly hems in our jungle fighters.

Cardinal tenet acquired by the Marines in their intensive training for tropical fighting is personal cleanliness. Medical and line officers repeatedly emphasize the necessity of keeping the body and clothes clean.

The battle is not peculiar—to the Marines. All the fighting forces must meet and solve the problem. But, because they are a swift, mobile force and thus can carry only essential equipment, the problem for them is more acute. . . . .

The way to cleanliness under such conditions, according to Navy Lieutenant Bruce W. Milligan, of Jacksonville, Illinois, is soap.

"When we bivouac over night, the men soak and wash the clothes they wore that day when possible in boiling water. They are chiefly particular about socks and underwear.

"We try to assure a bath a day for the men, a difficult task at best, since we're on the go and must depend on whatever water we can find or catch in the rain.

"With soap and water applied daily we can put up a successful fight against the fungi that fester the skin and open the path for infection. Soap is also the chief weapon against flies which menace health in the tropics.

"Men have been inculcated with the wisdom of sterilizing their mess gear in scalding soapy and clear water before and after eating.

"Malaria is a tougher nut to crack, but with this problem, too, great progress has been made. Atabrine has proved its value as a substitute for Jap-controlled quinine, and the men take daily doses. Every jungle fighter is equipped with mosquito net, a practical safeguard against the malaria-carrying mosquitoes of the tropics.

"Besides atabrine, the daily menu includes salt tablets and vitamin concentrate to supplement field rations. When possible, the medical officers purify the drinking water by chlorination, but for emergencies the men carry a tube of iodine to sterilize their own canteens.

"In the tropical humidity, cuts are slow to heal, organisms settle faster in the wound and cause it to fester. Such a common infection as athlete's foot, something you joke about in the States, will immobilize the infantryman unless treated. A coral cut suffered in landing operations or during swimming requires immediate attention or the Marine becomes a casualty.

"We know that disease is as much an enemy of the Japs as us, and we realize that the better we resist the disease axis, the better we fight the Japs. The men know that it is not enough to keep their rifles in perfect condition; they know that equal care must be given their bodies."—*Staff Sergeant Samuel E. Satvisky, Marine Combat Correspondent in Ill. Med. J*

IN MUCOUS MEMBRANE THERAPY

ARGYROL IS DIFFERENT

the DIFFERENCE—no irritation, no toxicity

the EXTRA FACTOR—physiologic stimulation of tissue defense function

NOT ONLY CONTRA-INFECTIVE

ARGYROL not only effects bacteriostasis without injury to tissue, it also produces decongestion without artificial vasoconstriction.

NOT ONLY CONTRA-CONGESTIVE

But there is a plus factor in decongestion and antisepsis with ARGYROL. This is physiologic stimulation of mucous membrane defense function. ARGYROL is stimulating to circulation, glands, tissues; soothing to nerve ends.

SAFE, NON-IRRITATING, EFFECTIVE

In 41 years of medical use of ARGYROL no case of toxicity, irritation, injury to cilia, or pulmonary complication in human beings has been described. Published independent pharmaceutical and medical surveys show that ARGYROL is by far the most widely prescribed drug for its indicated uses.

To insure your results, when you order or prescribe, please insist on the "ORIGINAL ARGYROL PACKAGE"

MADE ONLY BY THE A. C. BARNES COMPANY, NEW BRUNSWICK, NEW JERSEY

ARGYROL DETERGENT · PROTECTIVE · PUS-DISLODGING INFLAMMATION DISPELLING · SOOTHING STIMULATING TO GLANDS, TISSUE

Metamucil

REFLEX STIMULATION
OF BOWEL FUNCTION
THE "SMOOTHAGE" WAY

Metamucil provides a method of relieving colonic stasis in harmony with natural processes.

It avoids the harsh effect of irritating laxatives and roughage, the dehydrating and explosive action of salines, the leakage and vitamin-absorbing properties of oil.

The "Smoothage" Way . . .

—aids normal bowel function

—protects the mucosa against irritating food residue

The highly purified, non-irritating extract of Plantago ovata (Forsk) combines with a special dextrose base to mix easily with aqueous liquids. Palatable and acceptable to all patient types.

Indications—Chronic constipation, various forms of colitis, pre- and post-operative cases, hemorrhoidal conditions, the constipation of pregnancy.

Average dose—One rounded teaspoonful, stirred in a glass of milk or other liquid, followed by an additional glass of liquid.

Supplied in 1 lb., 8-oz. and 4-oz. containers.

Thirty-Seventh Annual Meetings

of the

District Branches

of the

Medical Society of the State of New York

PROGRAMS*

Third District Branch

Tuesday, September 21, 1943

Hendrick Hudson Hotel

Troy, New York

Afternoon Session

2:15 P.M.—Motion Sound Pictures: "Blood Transfusion," "Health in War"

3:15 P.M.—"Lesions and Abnormalities About the Mouth," lantern slide and motion picture demonstration
James E. McAskill, M.D., Watertown, New York

4:00 P.M.—"Postwar Problems in Tropical Diseases in Civilian Practice"
Col. Eugene R. Whitmore, Medical Corps, United States Army (Retired), Washington, D.C.

6:00 P.M.—Social Hour
Entertainment to be provided by the Woman's Auxiliary of the Rensselaer County Medical Society

7:00 P.M.—Dinner; Alson J. Hull, M.D., Toastmaster

8:00 P.M.—Address by Thomas A. McGoldrick, M.D., Brooklyn, *President of the Medical Society of the State of New York*

8:30 P.M.—"The Navy College Training Program"
Capt. Mark C. Bowman, United States Navy

Ladies will join with members of the District Branch for dinner.

Prize to Be Given

The Third District Branch will donate a prize of $25.00 to that Women's County Auxiliary from which county there is the largest percentage of physicians registered at this meeting.

Officers—Third District Branch

President.....Stephen H. Curtis, M.D., Troy
First Vice-President.....Homer L. Nelms, M.D., Albany
Second Vice-President.....John L. Edwards, M.D., Hudson
Secretary.....Harry Golembe, M.D., Liberty
Treasurer.....William M. Rapp, M.D., Catskill

Presidents of Component County Societies

Wednesday, September 22, 1943

Hotel Syracuse

Syracuse, New York

Afternoon Session

2:30 P.M.—"Common Diseases of the Skin," with lantern slide illustrations
Leon H. Griggs, M.D., Associate Professor of Dermatology, Syracuse University College of Medicine

3:30 P.M. to 5:30 P.M.—Symposium by the Department of Obstetrics

"The Use of Caudal Anesthesia in Obstetrics"
Francis Irving, M.D., Clinical Professor of Obstetrics, Syracuse University College of Medicine; Albertson Lippincott, M.D., Frank Meyer, M.D.

"Episiotomy—Recent Technics
R. J. Pieri, M.D., Clinical Professor of Obstetrics, Syracuse University College of Medicine

"The Significance of Vaginal Bleeding During the Third Trimester of Pregnancy"
Merton Hatch, M.D., Associate Professor of Obstetrics, Syracuse University College of Medicine

[Continued on page 1660]

* Programs of the First, Second, Fourth, and Eighth District Branch Meetings will appear in a later issue.

OPTIMUM NUTRITION FOR BABY...

MINIMUM TIME FOR DOCTOR...

with this complete liquid infant formula!

BIOLAC SUPPLIES milk proteins, milk minerals, iron, and vitamins A, B_1, B_2 and D in amounts which equal or exceed recognized requirements for infants. Thus with the sole exception of vitamin C, Biolac provides *complete* nutrition for the bottle-fed baby.

Biolac is a real timesaver for overworked doctors, too! *No carbohydrate or other extra formula ingredients to calculate!*

Also, with Biolac there is less chance of upsets due to errors in preparing formulas. Less chance of formula contamination, too, because Biolac requires only simple dilution with boiled water, as you prescribe.

NO LACK IN BIOLAC

Borden's complete infant formula

• *Biolac is prepared from whole milk, skim milk, carbohydrates—Vitamin B_1, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and sterilized. For professional information, write Borden's Prescription Products Division, 350 Madison Avenue, New York, New York.*

[Continued from page 1658]

"Recent Advances in Cesarean Section"
Vincent Hemmer, M.D., Associate Professor of Obstetrics, Syracuse University College of Medicine

"Control of Late Toxemias of Pregnancy"
Edward C. Hughes, M.D., Professor of Obstetrics, Syracuse University College of Medicine

If time permits, there will be showing of colored motion pictures of various obstetric operations.

Evening Session

6:00 P.M.—Dinner
Address by Thomas A. McGoldrick, M.D., Brooklyn, *President of the Medical Society of the State of New York*
Business Meeting—Election of Officers

8:00 P.M.—"Lesions and Abnormalities About the Mouth," illustrated with Kodachrome slides
James E. McAskill, M.D., Watertown, New York.

"Meningicoccal Infections"
J. Howard Ferguson, M.D., Professor of Pathology, Syracuse University College of Medicine.
Discussion by O. D. Chapman, M.D., Professor of Bacteriology, Syracuse University College of Medicine, and A. C. Silverman, M.D., Professor of Pediatrics, Syracuse University College of Medicine.

Ladies will join with members of the District Branch for dinner.

Prize to Be Given

The Executive Committee of the Fifth District Branch will donate a prize of $25.00 to that Woman's County Auxiliary from which county there is the largest percentage of physicians registered at this meeting.

Officers—Fifth District Branch

CARDIAC CLINIC DIRECTORY PUBLISHED

The New York Tuberculosis and Health Association recently published the Directory of Affiliated Cardiac Clinics, compiled and issued annually by the Association's Heart Division.

According to Dr. J. Burns Amberson, Jr., president of the Association. Affiliated Cardiac Clinics are those which have met the standard requirements of the New York Heart Association, of the New York Tuberculosis and Health Association. There are 41 such clinics located in New York City—22 in Manhattan, 4 in the Bronx, 10 in Brooklyn, and 5 in Queens.

Listed in the directory also are the vocational rehabilitation and employment services for cardiac patients in New York City, and the Cardiac Convalescent Homes available to residents of this city. These are: The Convalescent Home of the Burke Foundation in White Plains, Irvington House at Irvington-on-Hudson, the New York State Reconstruction Home in West Haverstraw, Pelham Home for Children at Pelham Manor, St. Francis Sanatorium for Cardiac Children in Roslyn, Long Island, and the Speedwell Society at 446 East 88 Street, New York City.

In his introduction to the directory, Dr. Irving R. Roth, chairman of the Committee on Cardiac Clinics, points out that as a result of the war, up to the present time 11 chiefs of the Affiliated Cardiac Clinics, as well as many staff physicians, nurses, and social workers have joined the armed forces. Others are expecting to be called in the near future. In spite of this, none of the Affiliated Cardiac Clinics has been discontinued, according to Dr. Roth.

1944 Reregistration of Physicians in New York State

From the State Education Department in Albany comes the following pronouncement which deserves the attention of all physicians in practice in New York State.—EDITOR

"The 1944 renewal application cards for annual registration will be mailed from the Department of Education on September 20, 1943. In the event that any practicing physician has changed his address without notifying the Department of Education, it is urged that he do so at once so that his renewal application card will be received.

"It is suggested that the application cards be returned to the Department as speedily as possible as the Department has been requested to furnish certain war agencies with lists of practicing physicians.

"A letter or reminder will be mailed to all physicians who fail to renew their registration on or before December 31, as required by statute. This reminder is to be mailed the latter part of January to those physicians who have failed to renew their registration and an additional fee of $1.00 will be assessed."

Rapid and pronounced reduction of stomach acidity

Creamalin promptly reduces stomach acidity. Moreover, the antacid effect is sustained.

With Creamalin there is no compensatory reaction by the gastric mucosa and no oversecretion of hydrochloric acid. Furthermore, there is no risk of producing alkalosis.

When employed with an ulcer regimen, Creamalin often induces unusually rapid healing of peptic ulcer.

Supplied in 8 oz., 12 oz. and 1 pint bottles

Medicine and the War

Rescue Service of Citizens Defense Corps*

THE Rescue Service of the Citizens Defense Corps is responsible for extrication of trapped casualties at incidents where there are no fires. At incidents in which the majority of casualties are trapped or buried, the Rescue Squads of this Service will assume the duties previously assigned to Stretcher Teams, in addition to performing the technical rescue work. (Operations Letter No. 133, "Organization of Rescue Service.")

Stretcher Teams, however, remain an essential part of the Emergency Medical Service. They have the following important functions:

(*a*) Assisting medical personnel at Casualty Stations in handling and nonprofessional care of minor casualties;

(*b*) Unloading ambulances and assisting in reception of casualties at hospitals; conducting the exchange of stretchers and blankets in order that ambulances may leave hospitals properly equipped;

(*c*) Assisting Mobile Medical Teams in handling casualties;

(*d*) Performing rescue work at incidents not requiring specialized Rescue Squads;

(*e*) Assisting Rescue Squads at major incidents at which many casualties are trapped.

The Chief of Emergency Medical Service should appoint a deputy charged with responsibility for the organization and training of Stretcher Teams.

Team Organization.—A Stretcher Team is composed of a leader and four other persons, preferably men or older boys, one of whom is designated as assistant leader. Team members are derived from the immediate neighborhood of the facility to which the team is attached. No member of a hospital staff who has any maintenance function should be selected for duty on a Stretcher Team.

Number of Stretcher Teams Attached to EMS Facilities.—Stretcher Teams should be attached to each Casualty Receiving Hospital and each Casualty Station. The number of teams attached to a Casualty Receiving Hospital should be determined in consultation with the administrator of the hospital, and should be based on the number of casualties the hospital is prepared to receive and the nature and extent of the duties the administrator expects team members to perform. The group attached to a Casualty Station should consist of two teams on call during the day and two on call during the night. On the basis of a previous Office of Civilian Defense recommendation, there should be one Casualty Station for each 25,000 persons and they need not be nearer than a mile apart (Circular, Medical Series No. 23).

Group and Team Leaders.—Stretcher Teams attached to any single facility of the Emergency Medical Service should be organized under a group leader. Group leaders are responsible, under general direction of the Chief of Emergency Medical service, for the organization and training of teams in their groups. They will conduct and supervise such drills as may be necessary; arrange hours on call; maintain rosters of teams and team members.

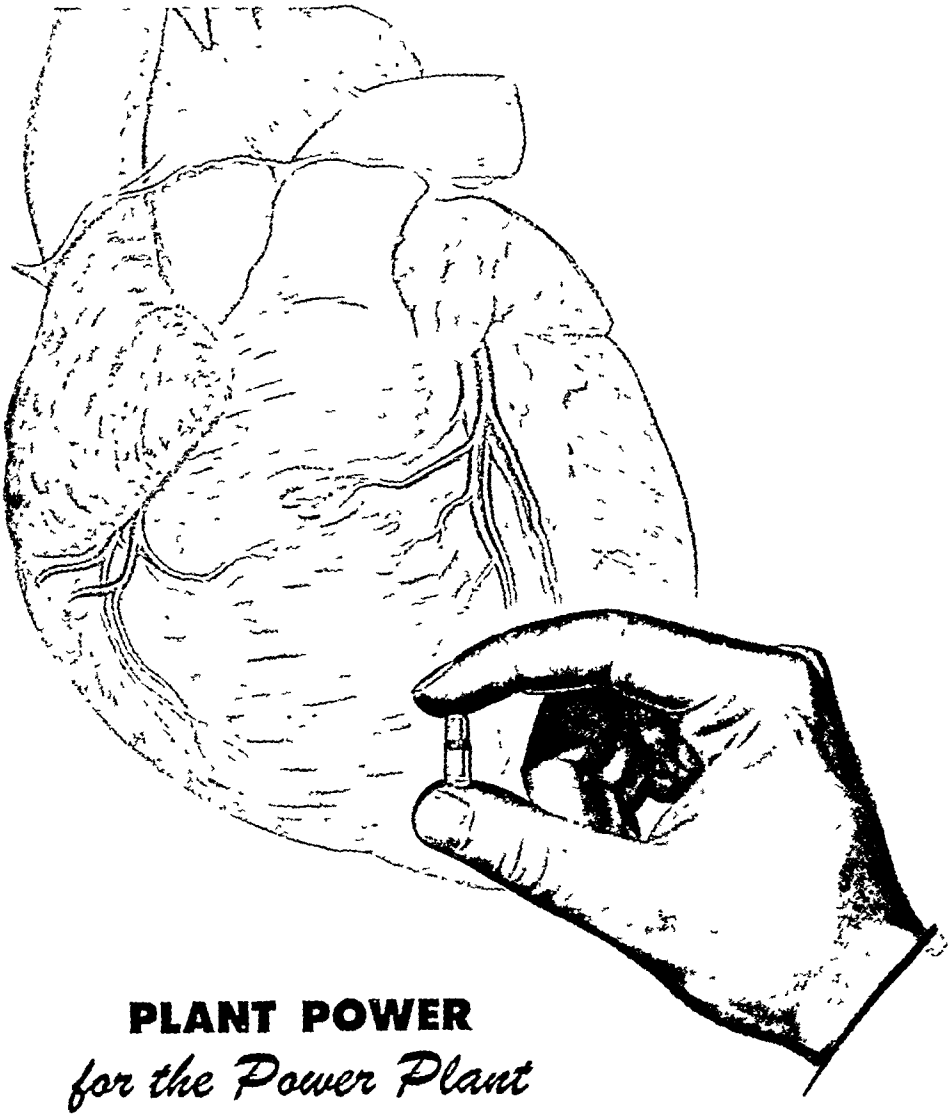
Group leaders will be appointed by the Chief of Emergency Medical Service. Team leaders will be responsible to group leaders for the organization and efficiency of individual teams. Leaders should be selected, so far as possible, from employees or residents of the building in which the facility to which they are attached is located. Both group and team leaders should be trained in first aid and stretcher technics. Group leaders should, if possible, have had experience in teaching first aid.

Mobilization.—Mobilization of Stretcher Teams on call occurs on the first audible public alarm. Mobilization of additional teams should be effected as these teams are needed or upon order of the control center. This mobilization should be accomplished rapidly according to a predetermined mobilization plan without recourse to public communication facilities and without requiring use of motor vehicles.

Control and Authority.—Stretcher Teams attached to Casualty Receiving Hospitals are responsible to the administrator of the hospital and are directed by him or such person as he designates. Teams attached to Casualty Stations are responsible to the administrator of the hospital to which the Casualty Station is related or to the physician in charge of the Mobile Medical Team at the Casualty Station when it is activated. At Casualty Stations not related to hospitals, Stretcher Teams are responsible to the physician in charge of the Station.

At incidents, Stretcher Teams are responsible to the physician in charge at the scene. If no physician is present, Stretcher Teams are responsible to the leader of the Rescue Squad, if such a squad is on hand; otherwise, directly to the Incident Officer or Senior Warden.

When needed in the field, Stretcher Teams will be dispatched from Casualty Stations and Casualty Receiving Hospitals on orders from the Control Center.



For incidents in the immediate vicinity of a hospital or Casualty Station, the physician in charge of a Mobile Medical Team may send forward a Stretcher Team to the incident on his own initiative.

Training.—(*a*) Preinduction: To qualify for appointment to the Medical Unit of the Citizens Defense Corps Stretcher Team members must meet the requirements of OCD Regulations No. 3, U.S. Citizens Defense Corps, by completing the basic twenty-hour Red Cross first aid course for civilian defense workers (Instructors Manual, ARC 1055) or the standard Bureau of Mines first aid course. If a Red Cross or Bureau of Mines instructor is not available, the course may be given by a qualified person certified by the Chief of Emergency Medical Service as an instructor.

(*b*) Postinduction: After enrollment in the U.S. Citizens Defense Corps as members of Stretcher Teams of the Emergency Medical Service, training is to be continued under general direction of the Chief of Emergency Medical Service in accordance with the training schedule outlined in the textbook, OCD Publication 2215, "Field Care and Transportation of the Injured," which will be distributed shortly by the Medical Division of the Office of Civilian Defense.

PLANT POWER
for the Power Plant

FROM seedling to harvest and on through processing and standardization contents of each DIGIFORTIS* Kapseal are handled meticulously. Careful supervision results in a medicament of highest therapeutic value, fat-free, containing *all* cardioactive principles of Digitalis leaf.

Air is excluded by hermetically-sealed gelatin capsules to guard against deterioration—to maintain in DIGIFORTIS Kapseals the most stable form of Digitalis.

Original potency of DIGIFORTIS Kapseals has been continued by use of the International standard and lethal dose frog method of assay. Each Kapseal represents 1 International unit, equal to 1½ grains of International Standard Digitalis, or 1 cc. (15 minims) of Tincture of Digitalis, International standard.

DIGIFORTIS Kapseals are supplied in bottles of 100 and 500. Other Digifortis products include ampoules, tablets and liquids.

OCD Urges Recognition of Health Officials in Civilian Protection Organization

IN ORDER that health and sanitation may be maintained during and after an air raid or other wartime disaster, health officers, with their deputies, division chiefs, and sanitary inspectors, should be members of the U.S. Citizens Defense Corps, the Office of Civilian Defense advises in Operations Letter No. 131, entitled "The Health Department in Civilian Protection."

Commanders of the U. S. Citizens Defense Corps are urged to appoint health officers to their staffs.

Health officers should develop plans for prompt action in emergencies to assure: (1) maintenance of safe water, food, and milk supplies; (2) sanitary disposal of sewage and putroscible waste; (3) sanitation at mass feeding centers, rest centers, casualty stations, billets, and other temporary facilities for war emergencies; and (4) control of communicable disease. Planning should include the mechanism for mobilizing essential personnel during and following an emergency, it is suggested. Another important duty will be to make arrangements for immediate instruction of the public in emergency sanitary measures.

In communities in which the health department does not have sufficient staff to provide sanitary supervision and inspection services in a war emergency, the health officer may select volunteer health deputies and recommend their appointment to the staff unit of the Citizens Defense Corps. The Operations Letter suggests that these deputies be persons with experience or training in public health, sanitary engineering, bacteriology, chemistry, and related fields. Tasks to which they may be assigned include supervision and inspection of disinfection of fractured water mains, pasteurization of milk, and preparation and handling of food at emergency feeding centers.

All health department personnel must complete training in accordance with regulations of the Citizens Defense Corps before they can become members, and, in addition, the health officer may prescribe special technical training for them after they have been duly enrolled.

A section of the Operations Letter is devoted to the place of state health agencies in the civilian protection program. State Defense Councils are urged to obtain the guidance and leadership of the state health officer in the development of an emergency health and sanitation program throughout the state. In states in which other agencies than the health department have responsibilities in health matters, it may be desirable to appoint a health and sanitation committee representing all the agencies concerned with health.

Nurses' Aides Eligible for Civilian Security Benefits

ALL Volunteer Nurses' Aides should be enrolled in the U.S. Citizens Defense Corps, the Medical Division of the Office of Civilian Defense states in a special announcement, Circular Medical Series No. 32.

The Circular explains that questions persist in some localities regarding enrollment, particularly of Nurses' Aides not specifically assigned to Mobile Medical Teams, Casualty Stations, and other field casualty units of the Emergency Medical Service.

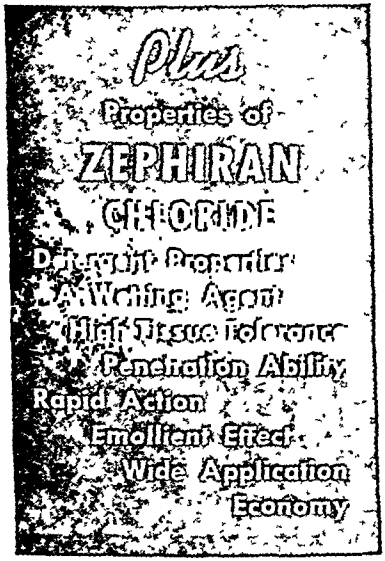
The immediate importance of this announcement lies in the fact that Nurses' Aides must be enrolled in the Nurses' Aide Unit of the Citizens Defense Corps, if they are to be eligible for the benefits provided under the War Civilian Security Program of the Federal Security Agency for all members of or trainees for the Citizens Defense Corps who may be injured in line of duty. Nurses' Aides presently working in hospitals and health agencies are considered to be in training for service in care of the wounded in the event of an enemy attack or other wartime disaster. They are therefore eligible for membership in the Defense Corps, and are thus eligible for the benefits of War Civilian Security after enrollment.

The Medical Division has recommended in various publications that Nurses' Aides be admitted to the Citizens Defense Corps when they receive their Red Cross certificates. It is suggested that the local Chief of Emergency Medical Service and the local Nurse Deputy arrange with the Red Cross Nurses' Aide Committee to have the required CDC oath administered at the graduation ceremony. All Nurses' Aides who have completed their training since the program was initiated but have failed to enroll in the Defense Corps should now become enrolled members. Women who are still undergoing their preliminary training as Nurses' Aides, but have not yet graduated, are also eligible for benefits if they are properly registered with the personnel officers of the appropriate Citizens Defense Corps as trainees for the Nurses' Aide unit.

A new arm insigne for outdoor dress, as distinguished from the emblem attached to uniforms, has been recently designed for members of the Nurses' Aide Unit of the Citizens Defense Corps. Nurses' Aides assigned to Mobile Medical Teams and Casualty Stations of the Emergency Medical Service may wear either this new arm insigne or the Medical Unit armband, but they must wear one or the other in order to move during periods of air raid alarm. The arm insigne will be distributed by the Red Cross in the same manner as the sleeve and cap emblem.

"DOCTORS AT WAR"

"Doctors at War," a one-reeler about doctors being trained for war in the Medical Field Service School under conditions of actual warfare, has been released by the Office of War Information Film Unit. The short was filmed at Carlisle Barracks, Pennsylvania, where the doctors, as student officers, are given a concentrated six weeks' course so that they can take their places with the combat troops.



ACCEPTED AMERICAN MEDICAL ASSN

Zephiran CHLORIDE

Brand of Benzyl Trialkonium Chloride

HIGH GERMICIDAL POTENCY

LOW TISSUE TOXICITY

A HIGHLY POTENT GERMICIDE with a low toxicity index is realized in ZEPHIRAN CHLORIDE, cationic detergent and germicide; a mixture of high molecular alkyl-dimethyl-benzyl-ammonium chlorides.

In an evaluation of germicides for clinical use by Hirsch and Novak,* using the phagocytosis inhibiting technic for determining toxicity, Zephiran Chloride was found to be germicidal in a 1:3970 concentration sterilizing infected blood completely, whereas the phagocytosis inhibiting concentration was shown to be 1:3370. The toxicity index of Zephiran Chloride thus is 0.85 as against an average of 5.2 for 70 per cent and 95 per cent alcohol and 900 for tincture of green soap.

Medical News

Navy Seeks Women Doctors

WOMEN doctors are now eligible for reserve commissions in the Navy Medical Corps, according to an official announcement made on August 10. The Navy Department at the same time started a drive to recruit 600 of them.

Reserve commissions as lieutenant commander, lieutenant, and lieutenant (jg) will be available, with 200 women to be commissioned in each rank, in accordance with first requests made by the Bureau of Medicine and Surgery.

Women doctors had been serving in the Women's Reserve where, even if they were doing regular Medical Corps work, their rank was restricted to that of lieutenant (jg).

The eight women doctors now serving with the Waves will be permitted to transfer to the Medical Corps.

Women doctors will be accepted in the Navy Medical Corps with the same status as male doctors, according to the Navy announcement, but they will be assigned to duty only within the continental limits of the United States. They will not be accepted, however, if they are the wives of Navy m or if they have children younger than 18.

They must meet the same professional requir ments as men and, to avoid undue depletion medical reserves in civilian communities, they al must be approved for military duty by the Procur ment and Assignment Service.

The general requirements for women physician are: For general medical officers, age limit, 21 t 35; for specialist medical officers, 27 to 50. Appli cants must be graduates of accredited medica schools and must have had at least one year's in ternship in an approved hospital. In addition, they must be duly licensed to practice medicine and have membership in a state or local medical society.

An exception is made for women who apply for commissions as general medical officers immediately on completion of medical school, when internship, license, and membership stipulations may be waived. Applicants for specialist commissions must have had at least three years' recent practical experience in a particular field.—*New York Times*

County News

Albany County

Dr. Thomas M. Holmes, of Delmar, has been appointed a member of the medical board of the State Employees Retirement System. He succeeds Dr. Clarence E. Mullens, of Albany, resigned.

A native of Albany and a graduate of Union College and Albany Medical College, Dr. Holmes enlisted in the medical corps of the United States Army in World War I but was lent to the British as a surgeon. He was wounded in France when a shell burst near the dressing station where he was working close behind the front lines.

Dr. Holmes practiced medicine in Bethlehem for a number of years.*

Broome County

Helping to meet an acute shortage of physicians, Dr. John Sassani, one of the few full-time industrial doctors in the Binghamton section, has resumed private practice on a part-time basis.*

Dutchess County

Dr. Louis Lipman, of Arlington, deputy chief and surgeon of the Arlington Fire Department, was honored recently at a reception held at the firehouse. About 60 members and guests attended the party given in honor of Dr. Lipman's recent marriage.

Fire Commissioner Howard Martin presented Dr. Lipman with a set of silver on behalf of company members.*

. . .

Clipped from the *Beacon News* of July 22—

"The *Poughkeepsie Journal* of Wednesday, March 29, 1797, had this news item: 'A meeting of physicians to organize a medical society will be held on May 1, 1797, at John Robinson's in Fishkill.' "

Greene County

Dr. Elwood Weisenburn is now associated with Dr. T. Earl McQuade, Coxsackie physician, and is already easing the pressure in that area due to a scarcity of doctors.

Dr. Weisenburn served his internship at Highland Hospital in Rochester after graduation from Albany Medical College.*

Jefferson County

Dr. George B. VanDoren, now serving his sixteenth consecutive year as health officer for the city of Watertown, has announced that he will retire from that office in October. He will then devote his full time to private practice.

Monroe County

On August 1 Monroe County Medical Society launched a series of radio programs which will continue through next June 27.

The opening program, the 495th consecutive broadcast of the Society, which claims the oldest continuously conducted medical broadcast in the United States, took the form of a roll call of various wartime services of the society.

Dr. Benjamin J. Slater will direct the 500th broadcast on September 5 and on January 3 Dr. Benedict J. Duffy, president-elect of the society, will be the speaker. Dr. Walter C. Allen, chairman of the health education committee, is program director.

Symposiums on various phases of the medical profession will be presented in the series, including war strain, with emphasis on its effect on the heart; new knowledge of medicine; food and nutrition; and scientific progress in the control of tuberculosis, cancer, and diabetes.

In another symposium, important socio-medical community services will be described by directors of these services, including child care and guidance, nursing, and social service.*

* Asterisk indicates that item is from local newspaper.

"don't smoke"...

is advice hard for patients to swallow. May we suggest, instead, *SMOKE "PHILIP MORRIS"?* Tests showed 3 out of every 4 cases of smokers' cough cleared on changing to PHILIP MORRIS. Why not observe the results for yourself?

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and interest to our readers.

REVIEWED

Operative Oral Surgery. By Leo Winter, D.D.S. Second edition. Octavo of 1074 pages, illustrated. St. Louis, C. V. Mosby Co., 1943. Cloth, $12.50.

This book should be highly valuable to both practitioner and student. It devotes chapters to chemotherapy, shock, burns, war wounds, dislocation and subluxation of the tempromandibular articulation, and pin fixation for the treatment of fractures.

The volume is replete with many drawings, illustrations, photographs, and x-ray reproductions which do much to clarify and make more valuable the written text.

FLOYD G. REA

The March of Medicine. The New York Academy of Medicine Lectures to the Laity, 1942. Octavo of 217 pages. New York, Columbia University Press, 1943. Cloth, $2.50.

These six lectures have the titles "Tuberculosis"; "The Brain and the Mind"; "The Freudian Epoch"; "Genius, Giftedness, and Growth"; "History of the B-Vitamins"; and the "Newer Knowledge of Nutrition." The lecturers were eminent authorities—Miller, Putnam, Brill, Gesell, Jelliffe, and Carlson.

The skill with which these distinguished men have adapted their language to the laity is something to marvel at. Their readers should greatly outnumber their hearers.

ARTHUR C. JACOBSON

Doctor in the Making. The Art of Being a Medical Student. By Arthur W. Ham, M.B., and M.D. Salter, Ph.D. Duodecimo of 179 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1943. Cloth, $2.00.

The authors have summarized their experiences as members of an advisory committee to first-year medical students at the University of Toronto. The book is an excellent presentation of a neglected subject and should be on the compulsory reading list of every student, premedical as well as medical.

All the enemies of success in medical school are discussed. Poor attitudes are thought to result from faulty conditioning in premedical school. Ineffective methods of study, inattention, faulty allotment of time, immaturity, etc., are all adequately discussed and the remedies suggested.

DUNCAN W. CLARK

Mental Health in College. By Clements C. Fry, M.D. Octavo of 365 pages. New York, Commonwealth Fund, 1942. Cloth, $2.00.

After the first World War, it soon became evident that the mental health of students is of equal, if not greater, concern to the community than the physical health of the students.

Yale University was one of the first colleges to establish a mental hygiene service for its students. The book deals with the experience of the psychiatrists who rendered that service at the University. It is a most illuminating presentation of the problems, generally emotional, that confronted the various types of students who sought help in the mental hygiene clinic, and the methods employed in their solution. It is a timely and instructive book that will find favor with psychiatrists, physicians, and educators. It is highly recommended to all who are interested in the development of wholesome personalities in our college population.

IRVING J. SANDS

Noxious Gases. By Yandell Henderson and Howard W. Haggard. Second and Revised edition. Octavo of 294 pages. [American Chemical Society Monograph Series.] New York, Reinhold Publishing Corporation, 1943. Cloth, $3.50.

The second edition of this monograph reflects the ever-increasing use in industry of chemicals which because of their volatility and toxicity constitute a constant hazard to the workers in a modern industrial plant.

Although not primarily concerned with the war gases, the chapters dealing with the irritant gases describe their characteristic properties and the toxic action of those which are used in industry as well as in chemical warfare. The greatest stress is placed on those chemical and physiologic principles which are of primary importance in the intelligent planning of preventive and safety measures. Directions for treatment are concise and specific.

ALFRED GOERNER

Virus Diseases. By Members of the Rockefeller Institute for Medical Research. Octavo of 170 pages, illustrated. Ithaca, N. Y., Cornell University Press, 1943. Cloth, $2.00.

The six chapters of this book deal with the following subjects: (1) Virus Diseases with Particular Reference to Vaccinia, (2) Chemical Structure and the Mutation of Viruses, (3) New Hosts as a Key to Progress in Plant Virus Disease Research, (4) Swine Influenza, (5) Human Influenza, and (6) Viruses and Tumors.

The presentation of these selected subjects by some of the most outstanding scientists gives an impressive record of recent progress in this fascinating field of investigation.

ULRICH FRIEDEMANN

Principles and Practice of War Surgery. By J. Trueta, M.D. Octavo of 441 pages, illustrated. St. Louis, C. V. Mosby Co., 1943. Cloth, $6.50.

This is a very timely book, inasmuch as it describes in detail the experiences of the author in the Spanish Civil War. His notable success in the treatment of war injuries by *débridement* and immobilization in plaster-of-paris whenever possible has revolutionized the treatment of war wounds.

The first part of the book is devoted to the consideration of the fundamental procedures of physiology, pathology, and bacteriology, in relation to war wounds.

The second portion is devoted to a detailed description of the methods used in treatment.

The book is excellently arranged and well illustrated. All who may have any part in the handling of the wounded of this war or in handling traumatic

SHARP & DOHME

ANNOUNCES

SULFAMERAZINE

Sulfamerazine, or 2-sulfanilamido-4-methylpyrimidine, is a new compound which will simplify dosage and lower costs in sulfonamide therapy.

Sulfamerazine was developed at the Medical-Research Laboratories of Sharp & Dohme and has been subjected to intensive pharmacologic and clinical examinations during the past few years. Supplies of this new drug will soon be generally available.

Rapidly absorbed... slowly excreted

In comparison with sulfadiazine, sulfamerazine is more rapidly and completely absorbed from the gastrointestinal tract and more slowly eliminated by the kidneys. Thus smaller and less frequent doses of sulfamerazine are necessary to produce and maintain therapeutic concentrations of the drug in the blood and tissues.

Moreover, free and acetylated sulfamerazine are more soluble in neutral or acid urine than are the corresponding forms of sulfadiazine. This fact, together with sulfamerazine's slow rate of excretion, diminishes the possibility of drug concretions in the urinary tract.

Small, infrequent doses

The less frequently required doses of sulfamerazine reduce sulfonamide therapy to its simplest, most economical terms. In diseases in which four to six doses of sulfadiazine (or other sulfonamide) are given daily, the same therapeutic results may be obtained with a minimum of inconvenience to the patient and at proportionately lower cost by only two to three doses of sulfamerazine.

•

ADMINISTRATION...Sulfamerazine tablets are administered by mouth in the treatment of infections caused by pneumococci, streptococci, meningococci and gonococci. Solutions of sodium sulfamerazine can be given intravenously.

Moreover, the smaller dose and longer retention of sulfamerazine have suggested the new drug's value as a prophylactic against certain infections. Sulfamerazine is no more toxic than sulfadiazine and appears to be safer, especially with regard to the possibility of urinary complications.

Supplied in 0.5 Gm. and 0.25 Gm. tablets. Sodium Sulfamerazine Powder (for intravenous solutions) is available in vials containing 5 Gm. Detailed information concerning sulfamerazine may be obtained upon request from the Medical-Research Division.
